

VOLUME

1

AN INTRODUCTION
TO WORLD HISTORY

WORLD HISTORY ENCYCLOPEDIA

CAROLYN NEEL, EDITOR | ALFRED J. ANDREA, GENERAL EDITOR

How to go to your page

This eBook contains 21 volumes. Each volume has its own page numbering scheme, consisting of a volume number and a page number, separated by a colon.

For example, to go to page 5 of Volume 1, type Vol1:5 in the “page #” box at the top of the screen and click “Go.” To go to page 101 of Volume 11, type Vol11:101 in the “page #” box.....and so forth.

World History Encyclopedia

VOLUME 1	An Introduction to World History
VOLUME 2	Era 1: Beginnings of Human Society
VOLUMES 3, 4	Era 2: Early Civilizations, 4000–1000 BCE
VOLUMES 5, 6	Era 3: Classical Traditions, 1000 BCE–300 CE
VOLUMES 7, 8	Era 4: Expanding Regional Civilizations, 300–1000
VOLUMES 9, 10	Era 5: Intensified Hemispheric Interactions, 1000–1500
VOLUMES 11, 12, 13	Era 6: The First Global Age, 1450–1770
VOLUMES 14, 15, 16	Era 7: The Age of Revolutions, 1750–1914
VOLUMES 17, 18	Era 8: Crisis and Achievement, 1900–1945
VOLUMES 19, 20	Era 9: Promises and Paradoxes, 1945–Present
VOLUME 21	Index

SECTION 1

Introduction and Preface

What Is World History?

Alfred J. Andrea and Carolyn Neel

Our purpose in creating this massive work, the *World History Encyclopedia*, is to provide intelligent laypeople, teachers, and students with a resource that will allow them to reach an understanding of the world in which they live. We offer a perspective that we believe will serve them well as they grapple with today's events and attitudes. First and foremost, we hope to assist them in developing a vision of the world as a human habitat, full of creativity, beauty, cooperation, brutality, choices, aptitudes, and attributes. We emphasize that a linear series of national, cultural, or geographical histories may have been considered world history in the past but is no longer a valid approach. Those elements are simply pieces of a mosaic designed to allow us to examine our world.

World history is as old as the putative “fathers of history,” Herodotus (fl. 450 BCE), Sima Qian (d. after 91 BCE), and the authors of Genesis. Each attempted to place the history of a particular people—Greeks, Chinese, and Israelites—into a far larger context, the context of the world as he knew and understood it. Beginning in the latter half of the twentieth century, however, a new historiographical tradition emerged, known as the New World History. Contemporary enthusiasm for world history, which is fast becoming global, initially blossomed in the United States in the aftermath of World War II and the Cold War that followed. People in the United States realized that isolationism was no longer possible or desirable. Consequently, interest in learning about other cultures and the interactions between societies led to an increasing interest in the study of world history. Such curiosity intensified as U.S. citizens realized, with some apprehension, that the “national” finances of the great American economic giant were intertwined with a global economic system. Three other phenomena were also at work. Demographically and culturally, the United States was clearly becoming far more complex and variegated after 1945, as immigrants from all over the globe swelled its numbers and enriched its social fabric. No longer was the standard Euro-American history a satisfactory response to the

question, “What are our roots?” With increased prosperity, higher levels of general education, greater leisure time, and faster modes of intercontinental travel, Americans were on the road to foreign destinations in numbers that multiplied almost annually, adding significantly to a growing awareness of and interest in the cultures of once-distant peoples. Then there was television and the other media of mass and fast communication that followed. Not only were Americans now able to view in their homes the cultures and histories of societies that once were largely unknown to the average university-educated American, but American culture was also going global and often returning to the United States in altered but interesting ways. One of many such manifestations of this development, which especially captivated young people, was (and is) Afropop, a blend of traditional African melodies and forms with Western music (much of which, in turn, had earlier connections with the music of Africa).

Most historians—certainly those who consider themselves students, consumers, or producers of works on world history—agree that this accelerating interest has been and will continue to be a good thing. Indeed, those who devote their lives to the discipline tend to be evangelical; some even believe that humanity’s very survival as a species depends upon our developing a nuanced understanding of the history of the world in which we live.

The discipline’s enthusiasts only begin diverging when they define their interests and methods of research and teaching. All agree on one issue. World history is *not* a collection of national or regional histories studied one after another. Put briefly, world history is a study of the past that transcends or crosses national, regional, and cultural boundaries. World history is also not, and can never be, the history of everything that has ever happened everywhere in the world. In order to be coherent and comprehensible, our remembrance, or reconstruction, of the past must be ordered and assembled with an end in mind. As is true of all historians no matter their specialty, world historians begin with specific questions and working hypotheses and subject those questions and hypotheses to exacting examination through careful analysis of available evidence. Only then do they venture to offer insights and to write their narratives. The only difference between the historian who focuses on a single nation, region, or cultural phenomenon and a world historian is the scope of the question and the narrative that follows.

When considering world history in the context of the discipline as a whole, it helps to think of a photographer in the field who carries a variety of lenses for a single camera. Some of those lenses are telescopic, allowing the photographer to capture distant objects. Others magnify minute objects that are close at hand but indistinct in their details to the unaided eye. Still others, known as wide-angle lenses, allow the photographer to take in vast panoramas. World history is analogous to that wide-angle lens.

The vast panoramas that world historians seek to describe include, but are not limited to, such issues as the ways in which societies across the world have come into contact with one another and cross-fertilized through a process of cultural interchange and adaptation. They also in-

clude a comparative, almost anthropological, approach to the past in which world historians study the different ways that diverse and often unconnected cultures have responded to similar stimuli. In addition to these three Cs—contact, cultural exchange, and comparative analysis—world historians are vitally interested in the ways in which societies across the globe have both cooperated and been in conflict with one another. One area in this regard that has become a rich field of inquiry for the new world historians is the study of borders and frontiers and the ways in which various societies have carried on complex relationships with their neighbors. Consider China, the self-described “Central Country” or “Middle Kingdom,” that has had a complex series of relationships with the many “peripheral” cultures along its borders. It is no wonder that China’s foreign relations loom large as a field of study for world historians. Simply put, world historians focus on historical *connections* on a grand scale. As already implied, that scale does not have to be global. For example, long-distance exchange of commodities and ideas along trade routes in the pre-Columbian Americas or similar commerce throughout Afro-Eurasia before 1500 CE have proved to be fruitful areas of investigation for many world historians.

Paradoxically, study of such grand vistas as, for example, exchange along the Silk Roads has also made world historians aware of the importance of many areas and cultures that were once considered obscure, largely peripheral to “real history,” and the province of only a few eccentric specialists working on arcane topics. One such area that is increasingly assuming a prominent position in world history studies is central Asia. No longer can it be seen as a great expanse of wasteland peopled only by nomadic pastoralists whose sole significant role in history was to occasionally raid and even overturn the states that ringed these great steppe lands, mountain ranges, and deserts that stretched from the Black and Caspian seas to Manchuria. To the contrary, the peoples, cultures, states, and even empires of central Asia are now coming into clearer focus (remember the historian as photographer?) and are being recognized for what they have been for many millennia: driving forces in the history of Afro-Eurasia.

Another paradox of world history studies is that the great majority of world historians, almost all in fact, also specialize in some discrete area of history. Most use their special area of interest, such as Tang China (618–907 CE), as a starting point for their world history studies. These two perspectives complement one another and result in a richer and fuller picture of both the localized field of inquiry (Tang China) and the broader field of study (Afro-Eurasia in the seventh and eighth centuries). To reiterate: all of the pieces are important, but they become world history only when assembled into the grand mosaic.

Preface: This World History Encyclopedia

Alfred J. Andrea and Carolyn Neel

We live in an exciting and complex world. The realization that we are interlinked with other countries economically, politically, and culturally has inspired us—as curious laypeople, entrepreneurs, concerned citizens, or academics—to search for greater understanding of societies with which we share this globe. We find the process of globalization alternately exciting and disturbing, depending on the events of the day and our individual convictions. This intensified concern with international connections inspired educators to develop core courses in world history, some in response to state directives. Instructors by and large embrace the task, yet these mandates necessitate broad resources. Our goal for the ABC-CLIO *World History Encyclopedia (WHE)* has been to provide an interesting and comprehensive resource that is accessible to the intelligent reader, whether layperson, student, or instructor. We wanted to promote a deeper understanding without assuming prior knowledge. We were determined to write plainly and avoid jargon but never to “write down” or oversimplify. History presents many unanswered questions, and good history writing must address the past’s ambiguities and uncertainties. We also embraced the necessity for historical truth by addressing the common distortions in our understanding of history sometimes introduced in more or less well-meaning attempts to encourage pride by inflating the nobility, wisdom, or status of our ancestors.

The *WHE* is the result of several big dreams, beginning in early 2002, in the minds of Ron Boehm, the CEO of ABC-CLIO, and Simon Mason, an ABC-CLIO acquisitions editor. Simon searched for an academic general editor who shared his vision of a comprehensible story of human history. After an extensive search, he recruited Al Andrea during the spring of 2003, and Al came on board in January 2004. Although Simon went on to address other challenges, we believe that the encyclopedia remained true to his vision. His proposal remained our basic founding

document and inspiration. By the summer, the team began to jell. Carolyn Neel was hired as project editor in October 2004, and that month Carolyn, Ron, and Al began working together in earnest to refine the design of the *WHE*. Al had already been recruiting era editors to manage the nine chronological periods that the work would cover. He enticed Wilfred (Fred) Bisson, William (Bill) Mierse, James Overfield, Dane Morrison, and Micheal Tarver early on, reserving one era, the fifth (1000–1500) for himself. Later, Al and Carolyn were able to convince Kevin McGeough, Jack Waskey, Mark Aldenderfer, Fred Nadis, and, after the project was under way, Alexander Mikaberidze who joined us later in heroic effort to bring the *WHE* to the finish line.

We began organizing our project. Early on we had realized that the rich complexity of world history does not allow for a standard A–Z organization of entries. Such a structure plays havoc with the concept of change over time and would confuse more than enlighten. We also knew from many years of teaching that organizing world history courses under strict chronological narratives does not work well. There is too much happening simultaneously in too many parts of the world. The story becomes lost in a rapid blur of dates, names, and event. Yet chronology is the basic metric that every historian must follow. B does not happen before A and cannot, in Whiggish fashion, be read back into the past. Whether we like it or not, the discipline forces us to construct chronological narratives. For that reason, historians have traditionally divided the past into coherent periods, or eras, and have provided them with titles, such as the “Age of Democratic Revolutions.” These categorizations have a useful purpose in that they tend to focus attention on specific aspects of the past rather than presenting a confetti of dates, places, and strange names. Unfortunately, these labels also predispose us—professionals as well as students—to look at periods of time through a preset conceptual lens, often blinding us to phenomena that run counter to the theoretical overlay. For example, a student exploring the world through the perspective of western Europe’s so-called Scientific Revolution might miss the reality that societies in this same era experienced a widespread efflorescence of emotional religious or romantic movements throughout Europe and the Americas. World history presents the would-be codifier of eras with an almost insoluble conundrum. How does one find a characterization to describe a period of time that would be historically valid across the world? After all, even in the twentieth century societies across the globe are confronted with different challenges and move at different paces.

Over the past 50 years, many creative schemas have evolved. Fortunately, if we took great care to emphasize to our readers that these arbitrary delineations were for conceptual convenience, not indicators of concrete global realities, the task had already been largely done for us. As Simon Mason pointed out in his proposal, in 1994 the National Center for History in the Schools, under Professor Ross Dunn of San Diego State University, developed a set of national standards for world history for grades 5–12. Those standards had sadly fallen victim to political controversy but were widely respected by historians. Realizing that periodization of world history was absolutely necessary despite its pitfalls,

Dunn and his collaborators devised a schema comprised of eight eras that, in our estimation, was sufficiently general and broadly valid as to work fairly well. They are Era 1, The Beginnings of Human Society; Era 2, Early Civilizations to 1000 BCE; Era 3, Classical Traditions, Major Religions, and Giant Empires, 1000 BCE–300 CE; Era 4, Expanding Zones of Exchange and Encounter, 300–1000 CE; Era 5, Intensified Hemispheric Interactions, 1000–1500 CE; Era 6, Emergence of the First Global Age, 1450–1770; Era 7, The Age of Revolutions, 1750–1914; and Era 8, The Twentieth Century. This was an excellent beginning, but we needed to slightly refine this “table of historical periods” in light of our twenty-first-century purposes and perspectives. Again, with Simon’s proposal as our guide, we decided on a nine-part structure: Era 1, Beginnings of Human Society to 4000 BCE; Era 2, Early Civilizations, 4000–1000 BCE; Era 3, Classical Traditions, 1000 BCE–300; Era 4, Expanding Regional Civilizations, 300–1000 CE; Era 5, Intensified Hemispheric Interactions, 1000–1500; Era 6, The First Global Age, 1450–1770; Era 7, The Age of Revolutions, 1750–1914; Era 8, Crisis and Achievement, 1900–1945; and Era 9, Promises and Paradoxes, 1945–present.

Despite these nine eras that serve as the encyclopedia’s most basic divisions, it made sense to us (and again, Simon’s initial vision was our guideline) to organize the eras along thematic lines. As already noted, it is not feasible to try to give a simultaneous account of every society in the world; students and instructors alike would drown in a sea of facts.

We turned again to the National Standards for World History, which calls for the development of five themes: social, political, scientific/technological, economic, and cultural (philosophical/religious/aesthetic). Recognizing current historiographical trends and anticipating future developments, in full consultation with the era editors, Al and Carolyn went a bit further, and we wound up with eight themes: (1) Population and Environment, (2) Society and Culture, (3) Migration and Travel, (4) Politics and Statecraft, (5) Economics and Trade, (6) War and Diplomacy, (7) Thought and Religion, and (8) Science and Technology. Each theme would be further divided into major topics, and each topic would be developed through short essays ranging in length from 600 to 2,000 words, depending on the significance of the item under discussion, and almost every essay entry would be accompanied by a sidebar (short secondary articles highlighting some aspect of the main essay). For example, under Theme 2, Society and Culture, a topic might be literature across the world in the period between 1000 and 1500. Essays under the topic might then deal with literature in Persia, Tamil India, Islamic India, Southeast Asia, Japan, China, Latin Europe, Byzantium, the Inca empire, and other significant areas of the world. Sidebars would be designed to put the human face on each entry, perhaps a passage from a Chinese poem, an example showing the role of troubadours in Europe, and so forth. In the process of commissioning desired essays, we often found ourselves with a nice variety of regional examples, with accompanying human-interest sidebars, but discovered that we still needed an overview essay to tie them together. Given that reality, we quickly realized that we would need thematic and topic introductions to tie the pieces together into a “world history” perspective.

Early on, the question of “voice” arose. Would we try to maintain a single voice across the eras, or would we embrace the “multiple voices” mode of presentation? Al, Ron, and Carolyn agreed that much of the joy and beauty of studying world history comes from lively exchanges—a multiplicity of voices and perspectives—both in the primary source materials and in the work of those who compile histories. We believed that an attempt at a uniform voice would dilute the representation of people from various social and economic levels, various genders, and differing cultural milieus. Trying to force everything into one narrative tone would strip away much of the richness. And, of course, there was always the issue of the “adopted voice.” Historians tend to take on the cadence and vocabulary of those whom they spend their lives studying. We wanted to preserve those voices from the present and the past. The many-voices decision enriched the encyclopedia in ways that we had not originally anticipated because it allowed scholars to write from their hearts as well as their intellects. History without passion is sterile.

So, having developed the basic philosophy behind the structure of the work, Al and Carolyn spent a long week in a Santa Barbara conference room discussing, arguing, shifting sides, revising, evaluating. How would we deal with uneven coverage of themes? For instance, in the era 1500–1750, there were many developments in the ways humans conceive the divine or transcendent—whole libraries have been built with worthwhile works on the topic—but how much can we deduce about religious (or any other) sentiments in the period from the first hominids until about 3500 BCE? We look at evidence and draw conclusion, but the conclusions are based on our own worldviews; the minds of the earliest humans are out of our reach. But wait. Educated speculations based on archaeological remains are worth considering, and perhaps “what we don’t know” is indeed as important as “what we do.” It was a stimulating, invigorating, and exhausting week. At its end, Al and Carolyn realized that there was much to say about every theme in every corner of the world in every era, but trying to impose an artificial consistency for the relative percentage devoted across eras to any theme would result in distortions. We decided to avoid inflating or flattening any theme’s percentage of the era’s total number of words just to maintain a proportional consistency.

The next week we refined our notes and sent them to the era editors, asking for outlines for their eras, structured around the skeleton we had developed. As they came in we analyzed them, looking at the percentage of the proposed text devoted to each theme, and found that instinctively the era editors had made appropriate adjustments; not all themes are equally important in all ages. For instance, Era 5 (1000–1500) might devote a bit larger percentage of copy to disease because of the Great Eurasian Pandemic (known in the West as the Black Death), which began in China about 1330 and spread across Europe in the period 1348–1350. Era 7 (1750–1914), on the other hand, which encompasses the Industrial Revolution, might spend a higher percentage on the impact of technology. Not all issues had the same importance across all eras.

We began a series of long bimonthly teleconferences, most attended by all of the era editors, refining our approach. Each conversation lasted

for more than two hours until one of us would throw in the towel by admitting that his or her head was about to explode, and we would schedule the next one. Questions arose, and we found good answers for most, superb answers to a few, and agreed to revisit others. An example: Fred Bisson, editor of *Era 4* (300–1000 CE), asked where we would situate essays on warfare. The social impact of war would logically fit under “Society and Culture”; technological and scientific changes or discoveries made during the effort to provide weapons of war went under “Technology and Science.” But where would narratives of specific wars and war leaders fit? Of course they would normally go under the heading “War and Diplomacy,” but we would have to be very careful to ensure that the war did not overwhelm entries about efforts at diplomatic solutions. The biweekly teleconferences continued for several months, then Al and Carolyn met again in Santa Barbara to sort through the outlines. We commandeered a conference room and pasted copies of the outlines around the space at eye level (Carolyn’s eye level, as tiptoeing is more difficult than bending a bit).

By the end of July 2005, we believed that the work was as well designed as was humanly possible. Nearly every aspect of human life through nearly the whole of human existence was at least touched upon if not fully covered. We looked for thematic examples across the world, from the development of earliest humanoids to the age of astronauts, from the northernmost settlements in Russia, Siberia, or Canada to the southernmost areas of South America and the semipermanent stations of Antarctica. The work was organized so that readers could trace one aspect of human history, such as women’s roles, throughout history; they could make direct comparisons of changes brought about by temporal, cultural, or geographic distance or any combination thereof. By reading any one theme throughout the various eras, readers could develop a deep understanding of an issue, such as changes in environment and population or in attitudes toward technology. Teachers could assign the era introductions to a class to help students get a big-picture view of the topics to be covered in a class. There were so many ways to sort and pursue their interests that we began thinking about creative ways of organizing the search functions on the electronic versions.

We basked in the sheer beauty of our design; actually, we spent a couple of hours basking. Now all we had to do was find folks to write it all up. And therein lay the problem. The will was there with many scholars. We had a very good response from postings in *H-World* and e-mail notes to colleagues at university history and anthropology departments. But in some areas, the scholarship just did not exist yet. In other areas, scholars simply had so many other commitments that they had no time to devote to this project. We struggled with Africa—plenty of great African scholars around—but many were booked up for the next two or three or ten years. We found three outstanding scholars who made time to work with us—Candice Goucher, Jonathan Reynolds, and Eric Gilbert—and eventually they either wrote the entries we needed or found colleagues to do so. But entries on more comparative topics, such as comparing economic conditions in eleventh-century southern Asia with those in Europe, were beyond our reach. Over the next year we

realized that few scholars were comfortable doing broad comparisons. Many of our entries—essays under a single topic—would be centered on specific parts of the world, perhaps one on India, one on Germany, one on the Incas, one on Japan. But as already anticipated, we needed to have a solid topic introduction to tie them together into a world history perspective by making explicit comparisons and looking at the broader view. Composing these topic introductions fell largely to the era editors, and it was a task that proved formidable but doable after much gnashing of teeth.

Not surprisingly, we also found that many of the most exciting entries were done by a contributor/editor team when young scholars—sometimes advanced graduate students—were paired with academic editors with longtime experience in their fields. The back-and-forth (or, even often push-pull) relationships produced fresh insights that were well anchored to a solid base of acceptable historiography. We had a sense of insight and adventure interspersed with exhaustion. Some days it seemed that it would never be done; other days the finish line seemed to be just ahead.

The *WHE* team grew both at ABC-CLIO and in the number of people who were willing to invest their time and expertise in the project. The era editors have been the finest, most collegial group possible and made the work a joy despite some frustrating times. The ABC-CLIO staff's names are listed in the front of this volume. Each brought a set of characteristics and abilities that kept the work exciting. The *WHE* could never have reached this point without the grace, intelligence, and dedication of the entire staff both editorial and the fine production staff under the guidance of Donald Schmidt, a gentleman and scholar himself. We also owe a special note of gratitude to many fine contributors such as William Burns, who hung in with us throughout the entire project. And Al and Carolyn want to add a special note of thanks to Ron Boehm, who pushed, prodded, and challenged but never lost faith in us, even when we ourselves felt on shaky ground. All in all it has been a wonderful experience, and we did in fact live through it.

SECTION 2

What Historians Do and Why They Do It

Introduction

Carolyn Neel

Deciding to write about the whole world, covering the entirety of human existence, is a heady task. After a period of exhilaration and wild enthusiasm, the academic editors and project editor realized that there were some issues, such as historiography, that needed to be considered outside the temporal confines of eras. We needed to provide some solid groundwork in two basic areas: historiography, discussed immediately below, and overarching issues, which we discuss in the next section.

With this section, “What Historians Do and Why They Do It,” we intend to give our readers a sense of the many ways historians can approach their tasks. A few years ago, some scholars thought that world historians were intent on discarding the more traditional ways of looking at history. Some may still think so, but you would be hard pressed to find a functioning “world historian” who has pursued such an agenda. Most of us realize that world history is but one of many valid perspectives, all of which are valuable in advancing human understanding of the past. In the following essays, a few brilliant theorists discuss their perspectives on the historiography of world history.

In this group of essays, we consider the ways in which historians operate—keeping firmly in mind that historians are a lively, contentious group. The term *historiography* literally means “the writing of history,” but among historians, discussions of historiography generally center on methodology and analysis. What is proper? What is useful? What techniques or methods will withstand the tests of time? Newcomers to the field might also ask about the ways in which approaches to a subject or the discipline as a whole changed through the decades. We developed the essays in this section particularly to consider the strengths and challenges of world history and recruited scholars who seemed to us able to offer a thoughtful, innovative approach to their topics.

In the first essay, Dr. Tom Laichas considers the differences between “world” and national or regional histories. The second essay could be considered a world historian’s answer to the charge of “revisionism.” Dr. Heather Streets discusses the reasons that we *must* challenge our

perceptions and practice the dread *revisionist history* from time to time as we expand our perceptions and realize that we must ask different questions. Changing perspectives on the past sometimes even involves changing our definition of evidence. Many years ago, a dear professor told me that “history” depended on written records; material records were “archaeology.” We’ve moved beyond that and realize that many things are best expressed through visual means, and, as Dr. David J. Staley shows, even cinema and video games convey information about our past. Furthermore, today, most world historians agree with Dr. Rick Szostak that we benefit from breaking down the disciplinary boxes and pulling in social scientists, climatologists, and others to help us widen our view. In the penultimate essay of the section, Dr. Luigi Cajani presents the widest view of all, the history of world history, which we think of as the view from the moon. Finishing up, Margaret Favretti talks about the challenges and joys of pulling it all together into a meaningful narrative for youngsters and teenagers.

Together, it is our hope that these essays will give our reader a taste of the various ways in which we can approach the subject, and—more importantly—an understanding that human life, past and present, is a rich kaleidoscope that we all can endlessly examine, interpret, and celebrate.

At one time, there were people who seemed to believe that scholars embracing the world history approach were intent on replacing traditional methods of studying history. As Dr. Laichas notes, world history—in all of its permutations—depends on the integrity of biographical, local, national, and regional studies. World history does in fact differ from national and regional histories, but it cannot replace them. World history can offer the grand overview of human existence, but world histories do not necessarily limit themselves to “big picture” perspectives; one could conceivably develop a world history of mundane items, such as cooking pots, and focus on the similarities and differences in those utensils across many societies. Most of those who focus on world history understand the importance of the detailed studies that underpin our understanding of the past. The goal is to build a mosaic that can be understood from many perspectives.

—Carolyn Neel

How Does World History Differ from National and Regional Histories?

Tom Laichas

Imagine a graduate student receiving an introductory world history reading list. The student finds a few titles suggesting “the world”: William McNeill’s *Plagues and Peoples*, Clive Ponting’s *A Green History of the World*, and Bonnie Smith’s three-volume *Women’s History in Global Perspective*. There may be articles too from the *Journal of World History*, the *Journal of Global History*, and *World History Connected*.

Yet the reading list also includes works whose geographic scope seems far more constricted. Judging from the titles, one book focuses on the eighteenth-century Atlantic, and another focuses on a single west African village. What, then, does “world” mean to world historians? Where is the line between world history and regional or national histories?

World Histories and Scale

The answer to these questions depends very much on whose world history we are talking about. The reading list imagined above represents what Ross Dunn has called the new world history. Most college courses reflect this approach; so too does the College Board’s Advanced Placement World History curriculum, offered to high school students throughout the United States.

At its grandest, the new world history understands the global past through the metaphor of the network or web. Sometimes called big history, this concept informs John and William McNeill’s *The Human Web*, David Christian’s *Maps of Time*, and Jared Diamond’s *Guns, Germs and Steel*. All these works argue that agriculture, technology, commerce, and

social structure have interacted over the past ten thousand years or more. Over time, these self-sustaining synergies have multiplied and intensified, expanding the geographic scope of human interaction.

A second approach, once called universal history and now comparative civilizations, understands history as the story of civilizations, each distinguished from the others by deeply embedded cultural, social, and political structures. With roots in the work of Georg Hegel, Arnold Toynbee, and Pitirim Sorokin, its recent exponents include Samuel Huntington, Matthew Melko, and Carroll Quigley.

A third framework is world systems theory. As defined by the American sociologist Immanuel Wallerstein, a world system is a hierarchically organized network in which a commercial or manufacturing core dominates its less developed semiperiphery and periphery. When Wallerstein first proposed world systems theory in the 1970s, he implied that the world system dates back no further than Europe's sixteenth-century American conquests. Janet Abu-Lughod's *Before European Hegemony* later argued that the Mongol empire, 300 years before, had an anchored polycentric world system of eight interlocking trade networks spanning all of Afro-Eurasia. A few years later Andre Gunder Frank and Barry Gills went still further, arguing that the modern world system had evolved over a period of 5,000 or more years, growing out of its roots in ancient Mesopotamia, the Nile, and the Indus.

World History and Regional Histories

Each approach to world history draws its own distinctive lines separating world, regional, and national histories. Civilizationist accounts often focus specifically on core regions and on the frontiers between them. For some, particularly Samuel Huntington, intercivilizational friction and conflict characterize frontiers. For others, notably Carroll Quigley, intercivilizational interactions lay the foundation for new civilizations.

Many civilizational models stress the importance of what E. L. Jones called the European miracle. While the new world history and world systems theory invoke geographic and environmental contingency to explain the rise of Europe after 1500, civilizationists—following in the footsteps of Adam Smith, Karl Marx, and Max Weber—stress what they argue are uniquely European traits (limited family size, wider literacy, Protestant-influenced economic philosophy, and a culture receptive to greater scientific, technological, and commercial innovation). In such accounts the regional focus shifts over time, from northern Italy in the thirteenth through fifteenth centuries to sixteenth-century Iberia and seventeenth- and eighteenth-century Holland, Britain, and France. This narrative migration from one civilizational core to the next informs, for instance, David Landes's *The Wealth and Poverty of Nations*.

For some time, advocates of world systems theory and the new world history blasted the Eurocentrism informing civilizational narratives. Edward Said's *Orientalism*, James Blaut's *The Colonizer's Model of the World*, and Andre Gunder Frank's *ReOrient* all sought, in Dipesh Chakrabarty's words, to "provincialize Europe."

World systems theorists have less use for regional studies than do civilizationists. By definition, the purpose of world systems analysis is to interrogate inter-regional patterns of trade and finance for what they can reveal about global economic hierarchies. In this view, modern states and regions are integral parts of one integrated world system. That said, world systems theorists have identified premodern peoples whose geographically confined economic interactions have created very small self-sustaining world systems.

One small-scale world system, that of California's Wintu people, functioned in a network of association that extended well beyond their immediate living arrangements. According to Christopher Chase-Dunn and Thomas D. Hall, this world system comprised merely around 1,850 square miles (4,800 square kilometers).

In contrast to both civilizationist and world systems approaches, the new world history takes particular interest in zones of interaction between human communities. These zones are characterized as much by cooperation, exchange, and (echoing Carroll Quigley) syncretism as by conflict. Unlike world systems analysts, new world historians consider cultural interaction just as important as economic exchange.

Twentieth-century French historian Fernand Braudel influenced this approach. Taking the Mediterranean rather than the European continent as a coherent region, Braudel argued in *The Mediterranean in the Age of Philip II* that sixteenth-century international politics were shaped by the inland sea's deep geographical and cultural past.

Braudel's study became a rough template for two generations of work. Thus, Philip Curtin and Bernard Bailyn have written on the seventeenth-century Atlantic system, K. N. Chaudhuri and Rene Barendse have written on the Indian Ocean, Arturo Giráldez and Dennis Flynn have written on the Pacific, and Anthony Reid has written on insular Southeast Asia. At the same time, a growing body of material has focused on continental zones of interaction: the Sahara-Sahel salt trade, the central Asian Silk Roads, and the turquoise roads linking the southwestern United States to the Mexican plateau. In all these studies, the term "region" refers to an economic and cultural crossroads, not a subordinate hinterland or isolated backcountry.

For some time, advocates of world systems theory and the new world history blasted the Eurocentrism informing civilizational narratives. Edward Said's Orientalism, James Blaut's The Colonizer's Model of the World, and Andre Gunder Frank's ReOrient all sought, in Dipesh Chakrabarty's words, to "provincialize Europe."

National Histories and World History

National history is the child of nineteenth-century nationalism. Since 1850, self-consciously modernizing states have mandated national history curricula from grade school to state-supported university coursework. To this day, most historians begin and end their careers as specialists in the histories of Japan, the United States, Iran, Russia, and other national states. Each national field subsumes all the history within the modern

state's geographical limits: the ethnically distinct Liao and Xiongnu states are part of Chinese history, while Indian history ranges over dozens of peoples, languages, and polities. Most historians, whether they have valorized or criticized the existing national narrative, reinforce boundaries within their discipline that coincided almost exactly with boundaries on the map. Very few possess the linguistic and methodological skills to undertake original research across large portions of the globe.

Though drawing heavily from such nationally based scholarship, world historians have criticized national histories on many grounds. Many national studies rest on the assumption that national history develops within its own territorial container, an "it" that may act or be acted upon but that over the centuries maintains an internal cohesion and identity. Yet as Thomas Bender has written of U.S. history, "the territorial space of the nation [is not] sufficient context for a national history. . . . National histories are part of global histories; each nation is a province among the provinces that make up the world."¹

This problem is particularly severe when national histories are read back into the distant past. This kind of history—particularly popular in the mid-nineteenth century but still very influential—asserts that modern legal systems, social networks, cultural conflicts, and national

character all incubate within the ovum of an ancient proto-national people. Such accounts can read like psychological case studies, as though they were reporting the childhood roots of the adult's heroism or psychosis. Mid-twentieth-century histories of Germany, Japan, Russia, Britain, and the United States were particularly prone to such thinking. Following Benedict Anderson's *Imagined Communities*, a generation of scholars has argued that nineteenth-century states invented ancient identities

Following Benedict Anderson's Imagined Communities, a generation of scholars has argued that nineteenth-century states invented ancient identities to legitimate their claims to expansive territories, classical cultural legacies, or prestigious cultural lineage.

to legitimate their claims to expansive territories, classical cultural legacies, or prestigious cultural lineage. Lately this debate has reopened, and historians are reexamining old questions. Was national identity really invented, or did it emerge from a preexisting ethnic/religious identification? Was it really invented by elites, or did these elite inventions merely build upon existing popular forms of communal identity?

Nineteenth-century national narratives also assumed that political structures developed predictably from clan through tribe to territorial state. And the development of political complexity, of state structures and administrative technique, fascinates world historians. Recent world history textbooks invite students to directly compare, for instance, Roman and Han administrative structures or eighteenth-century Japanese and French palace politics. Ambitious projects such as Victor Lieberman's *Strange Parallels* seek to understand why state building characterized so many early modern polities, from western Europe to Southeast Asia.

Yet as a group, world historians are skeptical of evolutionary schemes that place the centralizing state at the pinnacle of political development.

Many complex polities resist such neat categorization, among them the Hanseatic League, Mayan and Greek city-states, and West African forest kingdoms. The late-twentieth-century emergence of nonstate actors—commercial organizations such as the North American Free Trade Agreement (NAFTA) and the Mercado Comun del Sur (MERCUSOR, or the Southern Common Market), nongovernmental organizations (NGOs) like Amnesty International, and stateless religious-military-political movements like al Qaeda—have reminded historians (and everyone else) that paying too much attention to states, however defined, can seriously impair our understanding. Philip Curtin's investigation of cross-cultural trade networks, for instance, demonstrates the importance of nonstate organizations far into the past. Skepticism of national histories has led as well to studies of mapmaking. Relationships among cartography, national identity, and state political claims are at the heart of Laura Hostetler's work on the Qing, Thongchai Winichakul's work on Siam, and Jerry Brotton's work on early modern Europe.

World historians mine national histories to investigate one other topic: borderlands within nation-states. Over the past 20 years, U.S. historians Patricia Limerick, Richard White, and others have created a new Western history challenging the received image of a West settled from the East. In these narratives, indigenous, Mexican, east Asian, south Asian, east European, and African American peoples interact throughout the region's long history. Another strand of Western history links the region's economy to South America, Canada, Japan, China, the Philippines, and India. A zone of conquest, a zone of globalization, a zone of cultural encounter: the newly reimagined West was all of these. Studies of other frontiers and peripheries—Russia's eighteenth-century central Asian conquest territories, the Umayyad caliphate's eighth-century Persian frontier, and Argentina's nineteenth-century Chaco—have proven just as productive.

World History in Dialogue with Regional and National Histories

Perhaps the most important fact about the relationship between world and regional or national histories is this: regardless of theoretical perspective, world historians must—and do—read all three.

The reverse is not yet true. Historians of colonial New England, the Abbassid caliphate, or early modern Holland do not necessarily read world history. This entrenched localism impoverishes national and regional histories. It also impoverishes world history, which would benefit from the sustained attention of dedicated specialists.

Today we often hear politicians hurling the charge, “revisionist history,” implying that their opponents are misinterpreting history in order to serve their own agendas. Such charges, no matter their validity, inspire the question, “why do we change our view of history?” Sometimes, of course, it’s because we find new information that causes us to look at our past in a different way. At other times, it’s because we begin to ask new questions of the past. Should history be revised? Of course—we have not yet learned all we can from our past. As long as we face new circumstances, we will be inspired to look at different aspects of history. For instance, after the women’s movement, we started asking about women’s lives in past societies. The current controversy over immigration is causing more historians to ask about the past waves of immigration to determine the similarities and differences from today’s issues. So, let’s have a hearty round of applause for people, like Dr. Streets, who reveal that history is always a work in progress.

—Carolyn Neel

Ever-Changing Perspectives

Heather Streets

History is the study of change over time. But even the study of history has a history: since humans have begun to record the events of the past, their understanding of those events has varied widely depending on when they wrote, who they were, and where they were from. As a result, history is constantly being revised according to the time and the place in which it is written. An example of how historical understanding has changed over time can be found in the ways that twentieth-century American historians have interpreted the life and achievements of Christopher Columbus. Until the early 1970s, American historians wrote about Columbus in a relatively positive way, depicting him as an intrepid and courageous voyager who discovered the Americas and set the stage for the European migrations that were to follow in his wake. After the publication of Alfred Crosby’s *The Columbian Exchange* in 1972, however, this view began to change. Crosby demonstrated that Columbus’s arrival set in motion a chain of events that led to massive death and environmental destruction among the indigenous people, flora, and fauna of the Americas, and henceforth historians began to re-evaluate earlier interpretations. By the end of the twentieth century, few histories depicted Columbus as positively as in the past, and few ignored the catastrophic consequences of his voyages for the New World.

In addition to changing perspectives over time, each culture and social group has tended to view historical events differently based on their position in society or whether or not they were on the winning or losing side of conflicts. Consider the old adage that “history is written by the victors.” This maxim, though well worn, highlights the fact that dominant groups in history tend to have the greatest opportunity to tell their version of the past. It is probably no surprise, however, that such versions of history—whether told by elites, conquerors, or rulers—might differ substantially from the versions told by nonelites, conquered peoples, or vassals. These different ways of remembering, telling, and

writing about history over time and across space make it possible for each generation, each culture, and even each social group to see the past differently and to ask different questions of the past. This has certainly been true of the twentieth century, when historical events as well as changes in the historical profession produced a succession of shifts in the way history was researched, interpreted, and written.

From Ranke to the Annales School

Although individuals have been writing history for millennia, the academic study of history as most contemporaries know it today—involving the critical use of primary sources and the evaluation of different points of view—became institutionalized in European and North American universities during the nineteenth century. Influential scholars like the German historian Leopold von Ranke (1795–1886) shaped the discipline by insisting that historians use a wide variety of primary sources to present a picture of “the past as it really was.” In this way, historians were supposed to be neutral arbiters of “the facts.” Moreover, historians like Ranke believed that the most important “facts” to assemble were those of political, military, or diplomatic history; in other words, those “facts” that mainly concerned the great men and great events of history. By default, the everyday lives of peasants, workers, slaves, women, and marginalized people were left out of most historical works.

For the most part, academic history remained focused on politics, diplomacy, and war until well after World War II. Some historians, however, grew dissatisfied with Ranke’s priorities before the war. One group of these historians formed during the 1920s at the University of Strasbourg in France, and their work collectively became known as the Annales approach to history. The Annales historians rejected the Rankean focus on politics and war and instead concerned themselves with a variety of unconventional subjects, including the everyday lives of ordinary

The Annales historians rejected the Rankean focus on politics and war and instead concerned themselves with a variety of unconventional subjects, including the everyday lives of ordinary individuals, economic history, the history of attitudes, and history that exceeded the boundaries of nation-states.

individuals, economic history, the history of attitudes, and history that exceeded the boundaries of nation-states. For example, Lucien Febvre—one of the founders of the Annales school—published a book titled *Life in Renaissance France* that detailed the physical surroundings, spiritual beliefs, and social customs of ordinary French people during the Renaissance. In short, Annales historians like Febvre challenged the notion that history should only concern itself with high politics and great men by demonstrating that a multitude of subjects could be open to historical inquiry.

Why did some scholars begin to reject earlier models of history research and writing during the interwar period? Partly, responses like those of the Annales school reflected the evolution of the historical discipline itself, as researchers sought to differentiate their own work from

the work of previous historians. Yet part of the answer also lies in the devastating events of the interwar years. During this period, Europe was recovering from a world war that cost the lives of nearly 10 million soldiers. By the late 1920s, it was also seething with class conflict and reeling from economic problems that would only grow worse during the Great Depression. People all across Europe were fed up with the elite politics they believed caused the Great War and were deeply disenchanted with old attachments to class, station, and rank. In such an atmosphere, it is not surprising that some historians began to reject the elitism of history in favor of other emphases that could shed light on the history of ordinary people.

World War II to the Women's Movement

While the Annales school did not dominate academic historical study in the interwar years, it did provide inspiration for a new generation of historians who came to maturity after World War II. The war itself had devastated large populations all over the world: 60 million soldiers and civilians died, and countless more millions were left injured, hungry, or homeless. The trauma and expense of the war was also the death knell of the imperial era: in the three decades after World War II the Japanese, German, British, French, Dutch, Belgian, and Portuguese empires all collapsed. Colonial nationalist movements gained great strength in this period, involving the formation of massive political machines, civil disobedience, and—as in the case of Algeria, Indonesia, Angola, Mozambique, and Vietnam—protracted warfare.

One result of this imperial collapse was the appearance of scores of new nations in every part of the world, each with a need to understand its past anew. This was because prior to colonial independence, most academic histories about the various colonial possessions had been written by professional historians from the colonizing countries. The concerns of these histories, by and large, had been to tell the story of colonial conquest and to detail the lives of colonial administrators, colonial military officials, and imperial politics. Very few histories explored the lives or concerns of colonial subjects, and many depicted indigenous customs and history in a negative light.

Once independence was achieved, people in the new nation-states felt a strong need to produce histories that would explore the past from their own point of view. Their questions and perspectives, not surprisingly, were quite different from those of the colonizers. Instead of writing about colonial administrators and settlers, people of decolonized countries wanted to understand their precolonial histories, the mechanisms that colonizers had used to conquer and subjugate, and the story of their own mass movements and resistance to colonialism. For example, in 1957 the Indian historian Surendra Nath Sen published a book titled *Eighteen Fifty-Seven* that explored the history of the 1857 Indian Rebellion against the British. During the colonial period, British historians who had written about the movement depicted the Indian rebels as devilish fanatics or as incompetents. Sen's book sought to balance the

historical record by bringing to light the extensive atrocities that Britons carried out on Indian populations as well as the legitimate reasons that Indians resented the British presence. This kind of reinterpretation in all of the former colonies in turn opened up entirely new avenues of historical inquiry, fed by a hunger to recapture some of the past from the dictates of the colonizing powers.

Other events in the postwar decades led historians to broaden their focus from high politics, war, and diplomacy to more inclusive histories. One of these can be found in the struggles of oppressed and marginalized people to win basic civil rights in Europe and North America. Some of these movements were themselves inspired by colonial nationalist movements. By the 1960s in the United States, for example, American blacks had organized a massive civil rights campaign inspired in part by Mohandas Gandhi's ideas about civil disobedience and nonviolence.

Catholics in Northern Ireland, who were weary of being treated as second-class citizens by their Protestant neighbors, did the same in the late 1960s and 1970s. In the same two decades, many other groups organized in the name of civil rights. Indeed, student groups organized to protest the actions of their governments, labor unions organized to challenge what they believed were unjust laws and unfair labor practices, and

women's groups organized to work against sexual discrimination in the home and in the workplace. In all of these cases, ordinary people began to recognize and use the power of numbers to demand equal treatment before the law and to enact changes in government policy.

During these decades of unrest, protest, and change, many people began to realize—just as people in former colonial states had—that the conventional histories taught in school did not adequately represent the lives or the struggles of most people. For many, the history of high politics and diplomacy would no longer do; instead, they wanted to know about people like themselves, about the people whom history books and courses tended to ignore. This desire to ask new questions of history coincided with a gradual shift in the composition of professional histo-

rians in the decades after World War II. During the first half of the twentieth century, most academic historians were men from the dominant social group of their society. There were, of course, exceptions. Men like J. L. R. James and Eric Williams—both West Indians of African descent—wrote influential histories prior to the war, as did some colonial subjects, women, and American blacks. In the midst of decolonization and the movements for civil rights after the war, however, more women as well as men from previously marginalized groups entered the ranks of professional historians than ever before. This phenomenon was, in fact, closely related to colonial independence struggles and civil rights movements. As nations became independent, institutions of higher learning opened up to former colonial subjects, and far greater numbers of individuals were able to continue their schooling to the highest levels. In Europe and North America, civil rights struggles began opening universities to a much wider group of people, including people of African descent as well as women. As the numbers of these new historians grew, their concerns and questions began to shape historical scholarship. No longer were they interested in only telling the story of the dominant classes; rather, they wished to investigate the histories of the masses.

The result of all these changes was a dramatic shift in the writing of history toward studies that explored “history from below.” This shift took coherent shape in the 1960s in the form of social history—an approach to history that seeks to explore the everyday lives, concerns, and events of a wide variety of groups including women, the lower classes, and ethnic and religious minorities. Although social history could (and frequently did) involve politics, its practitioners also explored interpersonal relations, family life, local communities, and leisure, often from the point of view of oppressed or marginalized groups. An excellent example of the new social history was the English historian E. P. Thompson’s (1924–1993) 1963 book *The Making of the English Working Class*. This book sought to tell the story of the working-class movement that developed in England in the late eighteenth and early nineteenth centuries. Few of the people featured in the book were famous, although each contributed their own small share to what Thompson saw as a critical mass movement designed to better the lives of ordinary workers. The sources that Thompson used were both conventional and unconventional; while he investigated a variety of official sources, he sought answers to his questions also in folk songs, stories, and pamphlets. Following Thompson, numerous historians chronicled the lives and events of workers, peasants, and other groups underrepresented by earlier histories.

Related to—but nevertheless distinct from—the social historical concern with history from below was the development of subaltern history in postcolonial India. Social history tends to focus on a wide variety of underrepresented and marginal groups who nevertheless left some kind of written record behind. In contrast, subaltern history seeks to recover the histories of people who had no voice at all and who left virtually no written records. In precolonial and colonial India, these were the people who had no education and who were too poor to come to the attention of the state except in cases of famine or rebellion. Subaltern history involves both asking new questions of history as well as the creative

use of primary sources. Frequently, its historians have to read between the lines of official documents in order to recover the voices of such marginal groups. In addition, subaltern history has tended to be concerned with the power relations specific to colonialism, especially in documenting peasant insurgence and peasant resistance to colonial rule.

The concern of social history with historically marginalized groups, combined with the development of the women's movement and the entry of many more women into the ranks of professional historians during the 1960s and 1970s, also gave rise to the development of the coherent subfield of women's history. In many ways the women's movement developed directly out of civil rights struggles; as minority groups sought to realize equal treatment before the law, some women in Europe and North America began to see parallels between themselves and other minorities. In response, they began to campaign on their own behalf for equal rights to education and employment and launched lengthy—and ultimately successful—battles to open institutions of all kinds to both sexes.

Like former colonial subjects or men of marginalized groups from many countries, women who entered academia with an awareness of the struggle that it took to get there were hungry for histories that might shed light on the past of their own gender. They sought to uncover the voices and actions of women who had contributed to history but were forgotten, they sought to re-create what women's lives had been like at different times and different places, they sought to understand the mechanisms (ideological, institutional, educational, social, sexual) that have oppressed women in patriarchal societies, and they sought to show the different ways that women's roles have been conceived and constructed over time. By the early 1980s, women's history had become a vibrant field that had gone far in reconstructing a long-neglected past.

The Linguistic Turn

Yet by the late 1980s, a number of social historians—foremost among them many women's historians—began to realize that it was not enough to simply document the past of conventionally underrepresented groups. Rather, they argued that historical relationships must be fundamentally reimagined. For example, the women's historian Joan Wallach Scott argued in her 1988 book *Gender and the Politics of History* that gender, gender ideologies, and gender relationships were not sidebars to history but instead were, in fact, central to every kind of history, from politics and diplomacy through working-class movements. Because ideas about and relationships of gender shape language, practice, and economic realities, she argued that attention to the lens of gender would transform virtually any historical narrative from the way it has conventionally been understood. Indeed, by shifting the focus to gender, she demonstrated that new realms of historical inquiry based on ideology, belief, and unstated practices were possible. The historian's role, then, was no longer to be the neutral arbiter of "facts" but rather to decode the language and practices of the past to understand the ideological

structures underpinning historical events. After Scott, many other historians argued that this method of undertaking historical study was relevant for other kinds of lenses besides gender, especially the lenses of class and of race.

These massive changes in the ways history was being written, in who was writing history, and in what was being written about spurred some academics to condemn the credibility of social, subaltern, and women's historians. History, as it was conceptualized beginning in the nineteenth century, was supposed to be about "facts," told by an objective professional who was not personally invested in the story. That so many "new" historians were abandoning conventional subjects and methods was viewed in some quarters as a disturbing trend away from historical objectivity. Such historians, it was argued, were entering the profession motivated by their own personal agendas and then were publishing works based on those agendas. And if the stories of history changed according to who was telling them and through what prism they were being told, how could professional historians claim any special expertise on the past?

That so many "new" historians were abandoning conventional subjects and methods was viewed in some quarters as a disturbing trend away from historical objectivity.

The "new" historians, in response, increasingly argued that no historian—regardless of background—is capable of being truly objective because every individual is embedded in his or her class, race, and gender. Instead, they proposed that historians would do better to admit their biases openly rather than pretend to some standard of neutral objectivity. By the 1980s, this rejection of the possibility of objectivity was in full swing. In this project, historians borrowed from scholars of other disciplines—particularly philosophy and literature—who were focused on the frailty of language as a medium for conveying reality. They argued, indeed, that language was not a reflection of some inherently knowable historical reality but that language itself creates reality. As a result, historians influenced by what has become known as the linguistic turn argued that objectivity in historical writing was impossible because historians were using the faulty mechanism of language to structure a falsely ordered past from events and perspectives that were chaotic and unordered. Moreover, these historians subjected the texts and documents produced in the past to a new kind of scrutiny; now, not just the content but the language of the texts themselves were to be examined for the ways in which they structured the past. For example, Judith Walkowitz's 1992 *City of Dreadful Delight* explored how the language used by newspapers to talk about sexual danger in late Victorian London not only reported events that supposedly happened but in fact created new ways of thinking by establishing a common vocabulary for these subjects.

Many of the same historians influenced by the linguistic turn also utilized the ideas of postmodernism and post-structuralism in their work, each of which rejected a fixed and stable world of reality. According to these philosophies, reality is fragmented by multiple individual realities,

and there can be no grand narrative that accurately reconstructs it. Historians borrowing from these ideas began to argue that history itself can only ever be fragmentary and that the work of any individual historian can only represent a limited attempt to create order from a fundamentally fractured past.

At the turn of the twenty-first century, then, history writing looked very different than it had at the turn of the twentieth century. Historians had moved from a focus on “facts” about elite politics, rulers, and great events to “history from below” and from there to multiple histories and fragmented pasts. While these changes can be attributed partly to internal changes in the discipline of history itself, they are also quite clearly connected to the historical events of their time. In the future, historians may conclude that the linguistic turn and its related attention to postmodernism and post-structuralism were products of the uncertainties and anxieties produced by accelerated globalization as well as the destruction of the Cold War world.

Conclusion

In the twenty-first century, most historians are deeply aware that change over time and differences in perspective determine the way the past is—and has been—written about. For this reason, it is to be expected that each generation will have new questions about the past to research and answer. During the twentieth century, decolonization, civil rights movements, the women’s movement, and increasing globalization have spurred momentous changes not only in the way history is written about and interpreted but also in who is writing academic history. Moreover, there is every reason to believe that future events will spur further changes in the discipline and that future historians will revise history according to their own priorities and perspectives. Because of this, history is never simply finished; it continues to change with the humans who write about it.

In this essay, Dr. Staley considers the role of visual representation in shaping our thinking about history. He discusses the depictions handed down from the past that give us a sense of the time in a way that written words cannot. We also confront the question of modern media, such as movies and video games, some of which have been developed in such a way that they actually convey a sense of history. Can they have a valid role in developing students' awareness of the past? To discount such media as somehow too frivolous to be useful would be a disservice. When developed with care, these too advance an understanding of the past. This is a discussion well worth pursuing with an open mind.

—Carolyn Neel

Picturing World History

David J. Staley

One of the most popular video games on the market today is *Civilization*, in which a player develops a civilization from humble beginnings as a village into a mighty military, technological, and cultural power. The graphics are rich, including intricate maps and physical layouts of cities, realistic depictions of architecture and other building forms, human figures in costume, and statistics and other graphics to chart one's progress through the game. Video games like *Civilization* offer a rich multimedia experience of the past that many young people find very alluring.

Indeed, for many young students *Civilization* will be their most memorable experience with history, in the same way that an earlier generation of students was drawn more to films than to text. Consider the experience of watching a movie like *Saving Private Ryan*. Viewers of the movie can take in all at once the sounds and the sights of the advance on Omaha Beach during the Normandy invasion. With film, a viewer can see all the actions that are occurring simultaneously: here a mortar shell lands, there a squad disembarks, here a man cries out in pain, there orders are barked out, there a man grimaces at his wounds, here another's facial expressions show his fear. A reader of a textual version of these events must read the words one at a time in a line, since written language forces us to be linear with our descriptions. With writing, we must break up the simultaneity of the world into a sequential line: first this, then this, then this, and so on. As historian Robert Rosenstone observes, "Film lets us see landscapes; hear sounds; witness strong emotions as they are expressed with body and face, or physical conflict between individuals and groups . . . film can most directly render the look and feel of all sorts of historical particulars and situations—say farmworkers dwarfed by immense Western prairies and mountains, miners struggling in the darkness of their pits, millworkers moving to the rhythms of their machines or civilians sitting hopelessly in the bombed-out streets of cities."¹ These observations might explain the appeal of film and other visual media—these media allow us to take in

more information than what we can process with text. Video games represent the next step in the evolution of electronic media; with video games, in addition to the other affordances of film, the viewer can also be a participant. War games especially are becoming increasingly popular. Why merely watch a battle when one can actually “participate” in a World War II battle? Earlier generations of students asked their teachers if they could see the movie rather than read the text; we may well start hearing students ask their teachers “Can we play the video game?”

Movies and video games aside, history as it is practiced by professionals and taught to our students is largely a written discipline. The coin of the realm for a professional historian is a written monograph, a journal article, or a paper read at a conference. Historians prefer to transmit their findings by producing written secondary sources. While they may rely on visual primary sources in their research, the final product of that research is almost always a written representation of the past. While there are certainly other forms of representation in history—such as films, museums, the History Channel—and while these are all very popular forms of historical representation, they are largely marginalized by professional historians. By marginalized I mean that historians find them appropriate for teaching schoolchildren or the general public or perhaps appropriate for history buffs or for visitors to public history displays. These other forms of historical representation, however, are not accorded the same status as the “serious history”—like written history—practiced by professional historians. As the philosopher of history Hayden White once remarked, historians “are inclined to use visual images [merely] as a complement to our written discourse, rather than as components of a discourse in its own right, by means of which we might be able to say something different from and other than what we can say in verbal form.”² As we might expect, video games—even serious video games—are being similarly dismissed by professional historians as little more than popular entertainment but of no interest to the serious historian.

This attitude toward the visual has been enshrined in the historical profession for quite some time. In some ways, it dates back to the print revolution itself, as documented by Marshall McLuhan. The values that undergirded print culture reduced “serious knowledge” to that which could be printed in words. Pictures, oral tradition, and other forms of knowledge representation that had been so important to learning in the centuries before print were reduced in importance. Literacy—the ability to read and write printed language—became the hallmark of the educated person.

This tendency to value writing was especially evident among historians. At one time, those interested in the past would have been just as likely to represent the past in visual form as they would have been to write about it. Indeed, the impulse to picture notable events is as old as civilization itself, perhaps even older. Consider the following examples.

A mile deep into the caves at Lascaux, France, are paintings that are at least 15,000 years old. Some historians believe that these realistic depictions of bison, horses, and other animals are the commemoration of

Prehistoric painting of a bull with red and brown horses, found on the walls of Lascaux Cave in present-day Dordogne, France. Discovered in 1940, the cave is a treasure trove of Paleolithic-era cave paintings and petroglyphs. (Corel)

an especially successful hunt, a form of memory preservation in order to evoke more successful hunts.

Likewise with later civilizations, pictures commemorating significant events and triumphant stories were (and remain) an important form of public ceremony. Consider the Column of Trajan, a 100-foot marble obelisk with a long sequence of images spiraling upward, images that chronicled the Roman emperor's wars in Dacia during the second century CE. Arranging images in sequence as a way to tell a story is an ancient narrative form (familiar to anyone today who reads comic books).

Trajan's column depicts events of Trajan's campaigns in Dacia, located in modern-day Hungary and Romania. The column is located at the forum of Trajan in Rome. (David Bailey)

Construction of a fortified military camp at Hastings, from the Bayeux Tapestry, eleventh century. (Gianni Dagli Orti/Corbis)

The Bayeux Tapestry is a 200-foot-long visual narrative of the Battle of Hastings of 1066 that similarly juxtaposes a long series of images and written descriptions in order to tell a story.

The people of the sixteenth-century Toltec city of Cuauhtinchan drew cartographic histories, which were combinations of maps and stories. Notable events would be located on the map, but these stories moved along sequentially (not unlike Trajan's Column or the Bayeux

Cartographic history from the sixteenth-century Toltec city of Cuauhtinchan. (University of Texas Libraries)

Tapestry). Rather than moving in a line, however, the sequence of images meandered over the map.

The 14 Stations of the Cross that became popular in European (and later American) Catholic churches are a visual reenactment of the path that Jesus took toward his crucifixion. Pilgrims to the Holy Land continue to retrace this route, walking and praying along Jerusalem's Via Dolorosa (Street of Sorrows). For those who could not travel to the Holy Land, this event was abstracted, plucked from the specific location, and turned into a series of visual representations of the notable events along that route. The devout could experience the historical event in this vicarious visual fashion.

Court artists in the West African kingdom of Benin created bronze plaques that decorated the palace structures of the *oba* (king). These images would recount notable events in the life of the king or important rituals that demonstrated his power and authority. Michele Coquet observes that these court artists “organize and master the past with the aid of images composed by artisans with the help of court historians . . . the role of royal artists in this memory work is no less important than that of court chroniclers.”³

The birth of museums is to be found in the “cabinets of curiosities” of the sixteenth through eighteenth centuries. These were designed as rooms to display natural and man-made objects. The visual story of these collections was to show the evolution of humanity from nature to technology, the mastery of humanity over the natural world. These objects were arranged in such a way as to draw visual connections and comparisons among them. Arranging these disparate objects together within the physical space of the cabinet created an order, a visual narrative.

For generations, Pacific northwestern Native Americans have carved totem poles out of cedar. “To the Northwest Coast Indians,” writes Maryanne Kathleen Basti, “the totem pole provided a means of communicating their stories, myths and legends. The totem pole is an arrangement of symbols or memory devices in sequence created for the purpose of recalling a story or event. These symbols function as a form of ‘writing’—pictures, not written letters, convey meaning.”⁴ Like Trajan's Column, totem poles are visual stories, with stylized figures each representing a person, mythological figure, or event recounting the stories of families or clans. They are a form of collective memory.

Historical painting as a genre was particularly vibrant in Europe in the years between the French Revolution (1789) and World War I (1914). In this period, painters of historical scenes seemed especially interested in realistic and accurate portrayals of their subjects and often engaged in the kinds of research that historical writers engaged in.

Sixteenth-century bronze relief plaque from Benin depicts a nobleman and two attendants. Such plaques portrayed people and events surrounding the royal court and were mounted on the walls of the oba's (king's) palace. (Library of Congress)

At the same time, some historical painters were interested in interpreting the past as well, not just in trying to simply reconstruct it. In the same way that writers of historical works make interpretations based on word choice, historical painters make visual interpretations, as with David Wilkie's depiction of the news of England's defeat of Napoleon at the Battle of Waterloo. Rather than depicting the generals or scenes of the battle itself, Wilkie chose to represent common people and their celebrations of news of the event, which is a visual representation of social history rather than political or military history.

In 1765 Joseph Priestley (who is usually remembered as the discoverer of oxygen) drew one of the first time lines, a staple of any history classroom today. Priestley's first time line, a "Chart of Biography," plotted the lives of notable people. He later drew a time line of the "Principal Revolutions of Empire." "If a person carries his eye horizontally, he sees, in a very short time, all of the revolutions that have taken place in any particular country, and under whose power it is at present; and this is done with more exactness, and in much less time, than it could have been by reading." Priestley might have been referring to one of the most important properties of any visual medium: the ability to convey more information in less space and in less time. "I should not hesitate

View of a curiosities cabinet. From A series of illustrations . . . of Levin Vincent's collection of the marvels of nature. Haarlem: Sumptibus Auctoris, 1719. (Snark/Art Resource, NY)

to say,” he concluded, “that a more perfect knowledge of this kind of history may be gained by an hour’s inspection of this chart, than could be acquired by the reading of several weeks.”⁵

Mathew Brady documented the battles and other scenes of the American Civil War, one of the earliest examples of the use of photography to capture important events. Brady described his photographs as “a complete Pictorial History of our National Struggle.”⁶

Despite these and many other examples, histories of history rarely include these visual secondary sources and representations in their larger narratives. The typical story of the history of history begins with the Greeks, specifically Thucydides and Herodotus, who are widely credited with being the first historians because they sought objective answers (as opposed to appeals to myths or the supernatural) and wrote out their stories. David Hume famously remarked that “The first page of Thucydides is the beginning of all true history.”⁷ The typical account of the history of historical thinking then extends through the chroniclers, annalists, and historians of the Christian Middle Ages to Renaissance writers before extending to the creation of the professional discipline of history in the nineteenth century. Recently, historical writers from non-Western civilizations such as India and China have been added to the narrative, but only those civilizations that have a written tradition of historical memory are usually included.

The current professional practice of history had its origins in the nineteenth century, when history was firmly established as a written discipline and these other forms of visual secondary sources were relegated to the margins. Among several German historians especially, the dimensions of the professional practice of history were established, and in that professionalized form history was defined in terms of writing. Moreover, visual depictions were deemed lesser forms of historical knowledge. No one better expressed this new idea than Georg W. F. Hegel, who tied writing to the beginnings of history itself. Early peoples might have collected stories passed down orally over the centuries. “But it is the State,” wrote Hegel, “which first presents subject-matter that is not only adapted to the *prose of History*, but involves the production of such history in the very progress of its own being.”⁸ Early civilizations and the state structures that supported them required written records to maintain them, thus creating the necessary conditions wherein “the prose of History” could emerge. Historians have only recently begun to look again at visual primary sources as legitimate forms of evidence. However, visual secondary sources remain very much on the margin of our discipline (consider the fact that history on film is today considered as a controversial new subdiscipline).

In Western culture, as written text becomes the hallmark of literacy and education, images recede into the background, to serve as illustrations to the written text. We see here the birth of the visual aid whereby pictures support the text and are thus placed in a subservient role to the text. In Western societies, book illustration becomes a minor art (today it is associated strictly with children's literature), but at one time (in the medieval period in particular) diagrams and other illustrations were valued as intellectual arguments; philosophers and theologians accorded them the same status as a written argument. For a twelfth-century theologian such as Hugh of St. Victor, for example, geometric representations of knowledge (such as the diagram below) were the "fount of perceptions and the source of utterances."⁹

Among historians, images similarly recede into the background of historical texts. There are some excellent examples of these illustrations, which are largely ignored in the larger story of the history of history (and some might even say by students, who tend to see these merely as breaks in the blocks of text). The simple line drawings and sketches in the books of Hendrick van Loon, for example, were themselves meant to be visual interpretations. Look in particular at his depiction "The Real Congress of Vienna" from his book *The Story of Mankind*.

Not unlike the historical painters of the nineteenth century, van Loon is here making an interpretation of the event via his visual choices, in this case depicting the new diplomatic system that would organize European diplomacy in the nineteenth century as one being designed by only a few men. The emptiness of the room in which they work shows that this is not a system agreed to by the masses; democracy is not at work here.

Another notable example of these book illustrations can be found in the work of Bela Petheo, who designed the diagrams for William McNeill's classic world history textbook *The Rise of the West*.

In contrast to van Loon's drawings and the earlier tradition of historical painting, which were often depictions of events, Petheo drew animated charts of historical structures, as in this case with his depiction of the changes brought about by the shogun.

There is every reason to believe that history in the future will be even more visual and immersive than today's video games. Virtual reality immersive spaces are already prevalent today; three-dimensional reconstructions of ancient buildings and cities are already being produced, like the example of a virtual reconstruction of ancient Rome shown on page 39.

The tree of virtues, from the Psalter of Robert de Lisle, fourteenth century. (The British Library)

(William McNeill. The Rise of the West: A History of the Human Community, 1963)

Digital reconstruction of the ancient Roman Forum. (AP Photo/Rome Reborn project)

We should expect these reconstructions to become even more realistic and more interactive; in the not too distant future, you will be able to feel like you are walking around inside a famous building or along the streets of medieval London and interacting with people living and working in the city. (Think of this as like a living history museum made up of bits of digital information.) We are already getting a taste of this today; visit the Abraham Lincoln Presidential Library and Museum in Springfield, Illinois, to interact with a three-dimensional holographic image of Lincoln. Like the crew of the *Enterprise* on *Star Trek* who entered the Holodeck, history students in the future might learn about the past by experiencing a virtual re-creation.

Humans were preserving their history in visual form millennia before the first written histories were composed, and that ancient impulse—to picture the past—remains evident today. Whereas our earliest ancestors depicted the past on cave walls, today we see history represented in films and video games. By examining historical paintings, illustrations, cartoons, and museum displays we might learn something of how to think of world history visually. Images are not inferior to writing, and writing is not inferior to images. Rather, both offer different forms of representations that can be equally valuable in representing the past. Whereas someone like Hegel might have announced that “history begins with writing,” today’s young people—who have grown up on *Civilization* the video game—might be the ones who proclaim that “civilization begins with images.”

In this essay, Dr. Szostak considers the place of world history in the general mosaic of our knowledge of the past. The broad views of world historians rest on the meticulous work of archaeologists, anthropologists, biographers, political scientists, etc. Perhaps world history can best be envisioned as the view from the moon, a wider perspective that allows us to discover the range of choices in the human repertoire.

—Carolyn Neel

What Can We Learn from History? The Role of Social Scientists and Others

Rick Szostak

How does history fit within the broader scholarly enterprise? Can it, and should it, inform theorizing in the social sciences and humanities? Philosophers of history have long debated these issues. This entry will discuss in turn a number of arguments that have been made on both sides of these questions. World history naturally takes a comparative approach and is thus especially likely to yield insights conducive to theoretical generalizations. These debates regarding the role of history are thus especially germane to world history.

The Evolution of Social Science

It is worth noting first that the earliest social scientists, such as Max Weber, relied heavily on historical examples to support their theorizing. In the twentieth century, however, as governments collected more and more data, public opinion surveys became common, and methods of statistical analysis proliferated, social scientists increasingly came to focus on contemporary data instead. Yet the dangers in theorizing from such a limited set of experiences are obvious. It is all too easy to imagine a general relationship if one examines only quite similar circumstances: the vast sweep of history provides cases that would point to clarifications of theories that seem to fit modern experience reasonably well. As just one example, most theories of macroeconomic performance are unable to cope with the experience of the Great Depression. History is of particular importance for changes that occur slowly over long periods of time: theorists looking only at their own time will be unaware of such transformations. Finally, theorists can hardly understand occasional historical experiences such as revolutions or famines unless they widen their gaze beyond the postwar Western world.

In the closing decades of the twentieth century, many social scientists and humanists regained some interest in history, though they generally did so without much contact with historians in history departments.

Some social scientists, notably the Gulbenkian Commission in its *Open the Social Sciences*, thus embraced on the one hand the value of historical research to all social science disciplines while wondering on the other hand about the value of departments of historians. As shall be seen, they thus failed to fully appreciate the purposes of historical research.

Generalizations or Events?

Should historians seek the sorts of general rules that can inform theory (or indeed should they frame their arguments more formally in theoretical terms)? Alternatively, should they take as their purpose the explanation of complex historical events or processes? The Gulbenkian Commission, established by the Calouste Gulbenkian Foundation for the purpose of examining the state of the social sciences, took the first view. Most practicing historians focus upon the second. And philosophers of history have sometimes worried that an emphasis on generalizations would guide historians to ignore the study of complex events in the pursuit of highly focused historical minutiae. Yet the two approaches can be viewed as complements rather than substitutes.

The advantages of comparative research are discussed elsewhere. Briefly, historians can be more confident of their explanations of a particular event or process if these explanations also illuminate other events and processes. By extension, greater confidence is also appropriate for historical explanations that accord with well-founded theoretical generalizations. In turn, historians and theorists can be more confident of historical generalizations (or theories) if these in concert provide powerful explanations of particular events or processes. If a historian of the French Revolution still finds the Revolution mysterious after recourse to all relevant historical generalizations, this suggests that these generalizations are either misleading in important respects or fail to illuminate much that is important historically.

Case studies and comparative research are thus complementary. All types of historians should be interested in both types of research. Still, a historian located in a department of history is most likely to explore an event or process in its full interdisciplinary complexity.

One potential reason why generalizations may fail to explain particular events is that individual personalities played a decisive role. Yet here too historians can

Some social sciences emphasize how societies constrain individual behavior, while others stress the ways in which individuals shape their worlds. Though often viewed as substitutes, these two types of theory are increasingly seen as complements.

strive to generalize about certain personality *types*. Some social sciences emphasize how societies constrain individual behavior, while others stress the ways in which individuals shape their worlds. Though often viewed as substitutes, these two types of theory are increasingly seen as complements. Historians can usefully investigate both how societies

constrain individual behavior and how different personalities react to similar situations.

One concern of many contemporary historians is that the discipline is fragmented along geographic and temporal lines and also in terms of academic fields, such as social history, cultural history, military history, and so on. While these specializations are each valuable, there is no easy way to tie the pieces together. If history pursues generalizations in addition to the study of processes or events, then histories of different times and places are drawn together. If these generalizations address how cultural and social and other phenomena interact, then thematic subfields are united as well. A unified world history can thus be seen to depend on the pursuit of historical generalizations. Such generalizations will be easier to achieve if some consensus can be reached across fields with respect to definitions of the key phenomena of study (e.g., what is meant by “class”?).

Path Dependence

Path dependence implies that the path of historical evolution shapes the outcomes of historical processes. In other words, what happens today depends on what happened yesterday. The alternative perspective is that certain outcomes are inevitable: the best technology or institution or cultural attribute will eventually be chosen no matter what. It might be imagined that path dependence is incompatible with historical generalization. Again, though, the simple fact that each historical process is in certain respects unique does not mean that general rules are not in operation. Historians can draw on generalizations grounded in comparative research to understand why different societies follow different paths. These generalizations, in concert with path dependence, can help world historians understand why some ideas are adopted in one society but not another.

Can Complex Events or Processes Be Broken into Constituent Parts?

It is only possible to draw historical generalizations if complex events or processes are broken into constituent parts. It would be foolhardy, for example, to imagine that an event such as the French Revolution or a process such as industrialization would reoccur in identical form. It might be the case, however, that the relationship between peasant hunger and political instability or between factories and technological innovation is fairly similar across several historical experiences.

Some historians have wondered if complex historical events can in fact be understood in terms of such constituent arguments. Yet in practice, historians necessarily do this. A complex event can only be understood in terms of a series of more precise arguments. To be sure, historical narratives often stress how such arguments interact (as food

shortages and elite disharmony interacted in the French Revolution). It may be difficult in some historical narratives to fully distinguish different arguments. Yet it is generally possible, and arguably desirable, to frame any historical narrative in terms of a set of arguments that lend themselves to generalization. Michael Mann's *The Sources of Social Power* and Theda Skocpol's *States and Social Revolutions* are two of many books that have achieved considerable acclaim among both historians and social scientists by outlining a handful of key theoretical arguments and tracing their interactions through several case studies. Moreover, techniques have been developed to help historians diagram complex argument structures.

There is a strong minority tradition in both history and many social sciences that suggests that it is systems of causal relationships rather than individual causal relationships that should be the focus of investigation. Yet such systems—say, the capitalist world system—are not static but instead fluctuate, rise and fall, and (usually) eventually disappear. These changes in systems can only be understood by examining individual elements of the system. The historian can also usefully examine whether there are emergent properties of such a system that cannot be comprehended in terms of individual components.

The Question of Historical Bias

Historians in the early postwar years were forced by developments in philosophy to recognize that history as written was far from identical to either history as it occurred or history as it was recorded at the time. Historians necessarily bring some frame of reference to historical analysis with which they order their account. It was widely suggested by leading historians in the 1960s and 1970s that the best frame of reference was social science theory. However, if historians became involved in social science debates, they would become partisan and would be

likely to bias their historical accounts. The best path, then, it was argued, was to be minimally aware of social science theory and certainly never seek to contribute to theoretical debates.

It can be argued, though, that the best defense against bias is not disinterest but rather the clear statement of the arguments that one is making within a historical

It can be argued, though, that the best defense against bias is not disinterest but rather the clear statement of the arguments that one is making within a historical narrative.

narrative. While individual historians may be tempted to squeeze a particular historical account into a particular theoretical envelope, other historians can more readily expose such biases if the arguments are clear. Moreover, it is often observed in both philosophy and science that understanding advances best when there is competition among competing theoretical perspectives. If historians were to explicitly apply a range of theories to historical research, they could provide useful input to theorists as to which theories best fit which elements of the historical record.

When historians do use social science theory they have tended to apply only some theories, such as psychoanalysis or feminist theory, while ignoring others. This limits the ability of the historical enterprise to contrast one theory with another. Historians might often find that no existing set of theories does a good job of explaining particular events or processes. Historians might usefully suggest theories of their own or at least point to apparent commonalities across historical cases that need to be theorized.

Different theories posit different types of causal relationships. Sometimes a particular realization of one phenomenon may be necessary for a particular realization of another to occur (as in functionalist arguments that a state needs an army or armylike body). Sometimes one realization may be sufficient for another, or both necessary and sufficient, though it would seem that history is generally more complicated than this. In other cases, the effect may be positive or negative but neither necessary nor sufficient. In still other cases the outcome may be either positive or negative depending on other circumstances (or chance). When a system of relationships is studied, feedback may be positive or negative or unpredictable. Historians need to be open to these various theoretical possibilities.

Since disciplines tend to choose methods that are well suited to investigating their favored theories, historians in pursuing only a subset of theories may also be discouraged from applying the full range of possible methods. If, for example, historians downplay certain highly formal theories, they may underutilize quantitative methods. As with theories, different methods can be viewed as complements. Case studies can illustrate why some cases differ from the general relationships observed statistically, can explore how variables assumed to be independent within statistical analysis actually interact, and can analyze whether a correlation observed statistically represents causation.

The community of historians can limit scholarly bias by comparing and contrasting different theories and methods. In doing so, historians will also be able to provide the most useful input to social science theorizing by identifying precise circumstances in which different theories and methods excel.

Concerns Regarding the Quality of Social Science Theory

Historians might instead worry that most social science theory is so vague and general that it provides little guidance to the historian. Social scientists have indeed generally done a much poorer job than natural scientists of clearly stating under what conditions a particular theoretical generalization is expected to hold. This theoretical failure can be seen as an opportunity for historians. Historical research, and especially comparative historical research, can usefully identify circumstances in which a theory seems to provide insight and circumstances in which it does not. The historian's focus on the particular can thus guide theorists as to the appropriate range of applicability of any theory. Likewise,

historians in applying theories to circumstances quite different from those the theorist imagined may well suggest useful clarifications to the theory.

Scholars who identify themselves as world historians define their pursuits in many ways: some focus on contacts between societies and the impact that cultures have on one another; others focus on comparisons, for instance, comparing marriage practices or military organization among African, Asian, European, and pre-Columbian American societies. Perhaps it is easier to decide what world history is not. It is not a study of any societies in isolation, but it does not necessarily have to be the study of the entire world. Dr. Cajani discusses below the history of writing world history and considers some of the unique challenges of the discipline.

Writing World History

Luigi Cajani

Perched on the Moon

World history is variously defined by its practitioners, but one definition that is accepted by many is that world history is a comprehensive account of the human past, characterized by a threefold continuity: temporal, spatial, and conceptual. Temporal continuity means that the narrative proceeds chronologically, sometimes from the very beginning of human history. Spatial continuity means that it covers all the spaces of earth without privileging any geographical standpoint. This approach has been suggestively expressed by Leften Stavrianos, one of the founders of contemporary world history, as “the perspective of an observer perched on the moon rather than ensconced in London or Paris or Washington.” Finally, conceptual continuity means to give sense to this account by identifying common features to human societies worldwide.

A world history is therefore a coherent system, neither a collection nor an encyclopedic juxtaposition of separate particular histories, limited either in space or in time.

In the last three decades, interest in world history has been increasing among scholars, driven in part by a consciousness of globalization. But the drive toward an all-encompassing vision of the history of humanity is not new; rather, it has always accompanied historical thinking, in different forms and with different aims.

World History Begins at Sumer

As well as producing the first known literature, Sumerians produced the first written example of chronological and conceptual continuity with the *Sumerian King List*, whose first surviving text dates back to 2100 BCE. It is based on the idea that there is a unique legitimate kingship, established by the gods and passing from time to time to a different city. The list starts from the moment “when kingship was lowered from heaven” to the city of Eridu, with a set of mythical kings with very long reigns, lasting from a maximum of 64,880 to a minimum of 18,600

Babylonian map of the world, probably from Sippar, southern Iraq, 700–500 BCE. (HIP/Art Resource)

years. After 241,000 years the Flood swept over the earth, and then kingship was lowered again from heaven, this time to the city of Kiš: these kings ruled for much shorter periods, from a maximum of 1,500 to a minimum of a few years. Finally the list passes from mythical to historical kings, whose names are found in the historical records. The uniqueness of legitimate kingship is therefore the conceptual axis of the Sumerian view of history, and after the collapse of the last Sumerian dynasty, this model was adopted by such rulers of Mesopotamia as the Akkadians, Assyrians, and Babylonians. From Babylonian culture, we also have the first world map (dating from about 600 BCE, now in the British Museum), showing its geographical conception: the world is depicted as a circumference, occupied by Mesopotamia and surrounded by the sea, beyond which are seven islands.

This chronological continuity, based on a precise enumeration of years, was a particular feature of Mesopotamian historiography and is to be found also in the work of the Babylonian historian Berossos, a late-fourth-century BCE contemporary of Alexander the Great. Berossos published a history of Babylon in Greek and thus made Hel-

lenes and others immersed in Greek culture familiar with this vision of history. He identified ten kings before the Flood who collectively reigned approximately 430,000 years. The Hebrew Bible, or Tanakh, is also connected to the Mesopotamian vision. Genesis lists a succession of ten patriarchs before the Flood who also had mythically long lives, the oldest being Methuselah, who lived 969 years, and then continues through the history of the early Hebrews, with a precise account reckoned according to the passage of years.

Greek historians did not share this interest in an absolute chronology; instead, they widened the Mesopotamian geographical horizon to all the known world and inserted history into it, as in Hecateus of Miletus (ca. 550–ca. 476 BCE) and Herodotus of Halicarnassus (ca. 484–ca. 425 BCE), and developed two relevant conceptual paradigms: the pattern of the decadence of ages and the pattern of the succession of

empires. The former was formulated by Hesiod (who flourished in the seventh century BCE). In his *Works and Days* Hesiod lays out a Five Ages scheme, based on the Allegory of Metals: the first—and the best—is the Golden Age, followed by the Silver Age and the Bronze Age, each characterized by decreasing value and increasing violence. Then comes an age of heroes, the only one without a metallic reference

In his Works and Days Hesiod lays out a Five Ages scheme, based on the Allegory of Metals: the first—and the best—is the Golden Age, followed by the Silver Age and the Bronze Age, each characterized by decreasing value and increasing violence.

and that stops the trend of decline: heroes were semidivine, fought at Troy and Thebes, and were brought by Zeus to the Islands of the Blessed. Then follows the Iron Age, the present one, characterized by suffering, injustice, and hardscrabble lives. This vision was widely accepted in Western classical culture, from Plato to Ovid.

The idea of world empires is present in Herodotus of Halicarnassus, who identified the following ones, all related to Mesopotamia: Assyrians, Medes, and Persians. These were later put in a succession paradigm by Ctesias of Cnidus (fifth and fourth century BCE). In the time of Alexander the Great, historians added the Macedonian empire. Later, Roman hegemony in the Mediterranean led historians to add the Roman *impe-rium* as the fifth and last in this list. Thus, a five-empires pattern was established and became familiar in Greek and Roman culture.

The Christian Synthesis

Early Christian authors undertook the task of creating a new vision of history, the history of salvation, by merging the biblical narrative and the Greco-Roman historical tradition, and thus produced two main interpretation patterns that shaped the European vision of history until the eighteenth century: the pattern of Four Empires and the pattern of Six Ages. Before the advent of Christianity, the Greco-Roman pattern of the succession of empires was also to be found in the biblical Book of Daniel. In the first part, probably written about 250–230 BCE, Daniel interprets the dream of the king of Babylon: a statue made of metals of successively lesser value (the head of gold, a chest and arms of silver, a belly of brass, legs of iron, and feet made partly of iron and partly of clay), which is eventually destroyed by a stone. The theme reappears in the seventh chapter (written later around 164 BCE) with the vision of the four beasts. The identification of the statue or of the beasts with actual empires varied consistently among early Christian scholars, such as Saint Jerome (347–420) and Paulus Orosius (ca. 375–ca. 418), but there was a common agreement that four empires were indicated by the prophecy, the last being the Roman one, which was to last until the Second Coming of Jesus, put an end to it and inaugurated the kingdom of Jesus on earth. The Christianized Roman empire was given a providential meaning; the Pax Romana, the peace established by Caesar Augustus shortly before the birth of Jesus, was seen as the condition for the diffusion of the new religion.

Both beginnings and endings were significant in Christian lore, and consequently a branch of theology, known as eschatology, took shape that focused on the theological meaning of the Last Days and the ultimate destiny of humanity. The pattern of the Six Ages had for the early Christians a special eschatological significance. It was based on the tale of Genesis, according to which God created the world in six days, combined with the idea that for God one day is equivalent to 1,000 years, present both in the Hebrew (Ps 89 [90], 4) and Christian scriptures (2 Pet 3, 8). Therefore, the world was supposed to last 6,000 years until the Second Coming of Jesus. The biblical chronology, with its account

of the years since Creation, made possible predictions about the number of years left before the Second Coming. The reckoning was made difficult, however, by the fact that there was not only one text of the Old Testament but three: the Hebrew, the Samaritan (limited to the Pentateuch, or the first five books of the Bible), and the Greek translation called the Septuagint (Seventy Books). They showed relevant differences in chronology, both before the Flood and later about the kings of Judah and Israel. The ecclesiastical historian Eusebius of Caesarea (ca. 263–ca. 339) gave a synchronistic comparison of the three versions and calculated that according to the Septuagint, Jesus had started his public ministry in the 15th year of Tiberius, that is, 5,228 years from Creation, whereas the computation according to the Hebrew text gave 1,237 fewer years, and the one according to the Samaritan gave 935 years less. The debate on biblical chronologies absorbed historians' efforts for many centuries to come and well into modernity.

Saint Augustine of Hippo (354–430) strongly opposed eschatological calculations, asserting that only God knew when the end of the world would come. Nevertheless, Augustine accepted the model of the Six Ages, as in his *De Civitate Dei contra paganos* (*On the City of God against the Pagans*), which was written between 413 and 426. He established the following subdivision: the First Age went from Adam to the Flood, the Second Age went until Abraham, the Third Age went until David, the Fourth Age went until the captivity of the Jews in Babylon, the Fifth Age went until the birth of Jesus, and finally came the Sixth Age, the Christian Age, that included the present time and would last until the Second Coming of Jesus. Later the model of the Six Ages was adopted by Isidore of Seville (560–636) and by the Venerable Bede (674–735), who diffused Saint Augustine's periodization through their historical writings.

During the European Middle Ages the two models coexisted. The model of the Four Empires (also called the Four Monarchies) was adopted above all in Germany, for example in the *Annolied*, a poem probably written between 1077 and 1081 in honor of Anno II, bishop of Cologne, and by Bishop Otto of Freising (d. 1158), uncle of the Emperor Frederick I Barbarossa, in his *Chronica sive Historia de duabus civitatibus* (*Chronicle or History of the Two Cities*) because it supported the idea of the continuity between the old Roman empire and the new one in German hands and thus legitimated what became known as the medieval Holy Roman Empire. The model of the Six Ages was the more successful one: it is to be found, among others, in the *Libri Chronicarum* (*Book of Chronicles*) by Hartmann Schedel, published in 1493 in Nuremberg in Latin and German, that enjoyed widespread diffusion throughout Europe. In Schedel's hands, the Sixth Age melds the history of the Old Testament and the New Testament with the history of Rome, and the history of the Church and its popes and saints stands alongside that of the German emperors of the Holy Roman Empire. Moreover, alongside all of this, one finds the history of German and European cities and regions and of their most distinguished men. At the end there is the history of the future, the Seventh Age, opened by the coming of the Antichrist and closed by the Final Judgment.

Islamic World History

During the period known as the European Middle Ages there was a concomitant development of world history within the Islamic world. Muslim historians had a quite different horizon than their European colleagues, stretching from the Maghreb (western north Africa and Spain) to China. They were acquainted with Christian historiography, thanks to Christian historians working in the Islamic environment. Concerning periodization, Muslim scholars fundamentally divided history into two ages, before and after the *hijrah* of 622, the beginning of the Muslim era, when Muhammad journeyed from Mecca to Medina. Neither the Six Ages nor the Four Monarchies were relevant in this context. Great attention was given to the synchronization of the chronologies of the many cultures they met, however, and in some historians this issue had also an eschatological dimension, as it had for Christians. Abu Jafar Muhammad ibn Jarir al-Tabari (838–923) accepted the idea of the days of Creation to be equal to 1,000 years and concluded that Creation itself had lasted 7,000 years, and therefore the world after Adam would last 7,000 more years (*Tarikh al-Rusul wa al-Muluk* [History of Prophets and Kings]). On the contrary, in the tenth century Abual-Hasan Ali al-Masudi explicitly refused any calculations of the time from Creation and of the duration of the earth in his *Muruj al-dhahab* (*The Golden Meadows*).

Concerning periodization, Muslim scholars fundamentally divided history into two ages, before and after the hijrah of 622, the beginning of the Muslim era, when Muhammad journeyed from Mecca to Medina.

Europe Discovers New Spaces and New Histories

The European explorations suddenly and deeply changed the European vision of the world, of its geography, and of its history. A totally new part of the world was added to the three traditional ones (Europe, Asia, and Africa), and also the knowledge of these three dramatically increased through the reports of voyagers and missionaries. One can see an example of the outcome of the new knowledge in the work of François de Belleforest, who published in 1570 *L'histoire universelle du monde* (*Universal History of the World*). He did not follow any of the two medieval periodization patterns but instead combined a geographical (first Africa, then Asia and Europe, and finally the New World) with an ethnographical approach whereby the history of various peoples and countries was intertwined with the description of their present state. And the Dominican friar and utopian philosopher Tommaso Campanella (1568–1639) stressed the necessity of a new history that gave all the peoples in the world their share in the story. In his words:

The history of Humanity is of primary importance for politicians, orators and poets. . . . Let us read the particular histories of all nations: French, Spaniards, Germans, Britons, Ethiopians, Turks,

Moroccans. It would be necessary to collect the traditions of the indigenous peoples of the New World, who did not know the writing; and to collect what Chinese, Japanese, Tartars, Indonesians, Persians, Indians and other nations hand down concerning their own origins and deeds to posterity in written or oral form. . . . A complete universal history does not exist yet. (Pages 257–258)

Europe's two traditional chronological patterns survived nevertheless for a long time but with uneven success. The Four Monarchies became a new impulse because this model was adopted by Lutheran scholars, such as Philip Melanchthon (1497–1560), who worked in close contact with the historian Johannes Carion and whose *Chronicon Carionis* (*The chronicle by Carion*) became a most popular textbook, and Johannes Sleidan (1506–1556) in his *De quatuor summis imperiis* (*Regarding the Four Greatest Empires*), and so likewise did many Catholic historians, such as the Jesuits Orazio Torsellino and Antonio Foresti who wrote, respectively, at the end of the sixteenth and seventeenth centuries two successful reference works, the *Epitomae historiarum libri 10* (*Ten Books of Abridged Histories*) and the *Mappamondo istorico* (*Historical World Map*).

But freethinkers and Calvinist critics arose against this vision of holy and profane history. Jean Bodin, censored by Catholics as a heretic, rejected in his *Methodus ad facilem historiarum cognitionem* (*Method for the Easy Comprehension of History*, 1576) the eschatological interpretation of the Four Monarchies as “an inveterate mistake.” And John Calvin in his *Praelectiones in Danielelem* (*Lectures on [the Book of] Daniel*, 1561) stated that the Fourth Monarchy was, indeed, the Roman empire but that it had ended with Jesus.

Among Lutherans a new historiographical pattern emerged in connection with the idea of a *media aetas*, *medium aevum*, or *media tempestas* (all meaning “middle age”) of decadence, and the idea became a pillar of anti-Catholic polemic. This idea of a degenerate middle period of history between antiquity and the present had been initially conceived by humanist scholars to describe the time in which the putative decadence of classical culture took place, but the Protestants extended it to the decadence of the Church and hence to the whole of human history. The new periodization of ancient, medieval, and modern history was subsequently systematized in the late seventeenth century by the German historian Christoph Keller: the current Eurocentric scheme of history periodization had thus taken its form.

Tommaso Campanella, one of the first to develop a global vision of history, engraving by Sebastian Furck in *Bibliothecae Chalcographicae*, 1654. (Stapleton Collection/Corbis)

The End of Biblical Chronology

In the mid-seventeenth century biblical chronology was still an issue, and Moses, the supposed author of the Pentateuch, was still considered the first historian. Anglican archbishop James Ussher (1581–1656) put a milestone in the reckoning with his huge work *Annales veteris testamenti, a prima mundi origine deducti* (*The Annals of the Old Testament from the Beginning of the World's Creation*, 1650) in which he fixed the date of Creation at 4004 BCE on the basis of the Hebrew Bible and thus established a tradition accepted also in the Catholic world. But in the same period this Christian chronology was for the first time seriously questioned by new historical information coming from the East. Catholic missionaries, especially Jesuits, were providing new knowledge from within Indian, Japanese, and Chinese cultures through the study of their languages and histories. In 1658 the Jesuit Martino Martini published an account of Chinese history, the *Sinicae Historiae Decas prima* (*The First Ten Books of Chinese History*), based on Chinese sources, where he presented a chronology that was much more ancient than the Hebrew biblical one, a chronology that could not be easily disregarded and rejected as mistaken because, in his opinion, Chinese historians were highly reliable. The conflict between the Chinese and biblical chronologies unleashed a great debate among European scholars that continued during the eighteenth century, and one of the consequences was the admission of China onto the European historical horizon. One of the most relevant outcomes was Voltaire's *Essay sur les mœurs et l'esprit des nations* (*Essay on the Manners and Spirit of Nations*, 1754) in which China became a positive protagonist of history. In the foreword Voltaire pronounced a blanket condemnation of the latest "champion" of the old universal model of history inspired by the Christian religion, Bishop Jacques Bénigne Bossuet, who had published *Discours sur l'histoire universelle* (*Discourse on Universal History*) in 1681. Voltaire took the *Discours* as an example of the wrong approach to history writing:

The conflict between the Chinese and biblical chronologies unleashed a great debate among European scholars that continued during the eighteenth century, and one of the consequences was the admission of China onto the European historical horizon.

That renowned Bossuet . . . in making reference to the Arabs, who founded such a powerful empire and so thriving a religion, only says that they were a flood of barbarians. It looks as if he wrote history only in order to claim that everything that happened in the world has taken place for the sake of the Hebrews. . . . [I]t would have been desirable that he had not completely forgotten the ancient peoples of the Far East, such as the Indians and the Chinese, who were so important even before other peoples had yet come into existence. (Pages 240–241)

The Eurocentric Christian vision of history was definitively challenged. A great contribution to the renovation of historiography came with the English collection *An Universal History, from the Earliest Account of Time to the Present: Compiled from Original Authors*, a huge set of 23 volumes in-folio first published in London during 1736–1764. It soon had a great success in Europe, with many translations and often with important additions and revisions. This work provided historians an unprecedented treasure of sources and information on the history of almost all peoples of the world. One of the translations was made in Germany at the University of Göttingen, a stronghold of the Enlightenment, whose historians gave a great impulse to the development of the new world history. One of the most prominent among them was August Ludwig Schlözer, who in the foreword of his *Vorstellung seiner Universal-Historie (Presentation of his Universal History, 1772)* pinpointed ethnocentrism as the principal bias and obstacle in writing a well-balanced history of humanity:

World history takes into account all the states and all the peoples in the world. Without fatherland, without national pride, it covers all the countries where human societies dwell and embraces with its eyes all the scene where human beings played their role. All parts of the world are equal to it. It has no predilection for the Four Monarchies, which pettily put aside about thirty more, nor for the people of God, nor for the Greeks and the Romans. Its interest reaches the Huang He river and the Nile, just as the Tiber and Vistola; Ilidschuzaj is for it more important than Maecenas, Alexander the Great, Caesar and Gustav Adolf are not more important than Attila, the Incas, and Timur Lenk. (Page 28)

Schlözer maintained that world history should not be a loose *Aggregat* (aggregate or collection) but instead should make up a coherent *System*. His rationale was based on *Hauptvölker* (main peoples), divided into *herrschende* (dominating peoples) and *blos wichtige* (merely important peoples). The former were the peoples who had determined the course of history for millions of human beings either as conquerors or as legislators. The latter were the peoples who, without violence but only through wisdom, inventions, commerce, religion, superstition, or chance, gave rise over long periods of time to the fundamental changes affecting most of humanity. Schlözer's universal history had an essentially Euro-Asiatic bearing: Africa only appeared with the Egyptians and the Carthaginians, and America was completely absent. But soon other German historians widened this horizon, such as Johann Christoph Gatterer and Johann Gottfried Eichhorn, who gave a great space to America and Africa. A new secular and non-Eurocentric world history was thus born, in consonance with the cosmopolitan view of the Enlightenment, as expressed in those years by Immanuel Kant in his *Idea of a Universal History* (1784).

The Christian chronology in Ussher's version was still accepted, but another definitive stroke was arriving, this time not from inside historical scholarship but rather from outside, thanks to a development in

the natural sciences, namely geology. In 1778 the comte de Buffon published *Les époques de la nature* (*The Epochs of Nature*), which attributed at least 75,000 years to the age of earth. Shortly afterward, in 1788, James Hutton presented to the Royal Society of Edinburgh his *Theory of the Earth* in which he went far beyond Buffon, attributing millions of years to the planet. The end of Christian chronology had thus begun. One can find a sign of this in a later work by Schlözer, the *Vorbereitung zur Weltgeschichte für Kinder* (*Introduction for World History for Children*), in which, unlike in his work of 1772, he expressed skepticism about traditional chronology: “God created once the world from nothing. At what time did He create it? Nobody knows: possibly what we call the ‘world’ is many hundred thousand years old.” (Page 1)

Eurocentrism Strikes Back

The cosmopolitan commitment to writing a world history “without fatherland, without national pride” could not accommodate nationalism, which spread all over Europe and the Americas during the nineteenth century. The dominating idea, strengthened by the new colonial imbalance of power, was the superiority of Europe over the rest of the world, and the superiority of one’s own nation inside Europe. Georg Wilhelm Friedrich Hegel in his *Philosophy of History* (1837) developed a paradigm of world history based on the development of the Spirit toward the fulfillment of freedom. China was not anymore a model civilization but was only the first stage along this path, because in China only one man, the emperor, was free; then came the Greco-Roman world, where only a few men were free; and then the last and final stage, the German world, where everyone knows that he is free. This idea of German superiority is also to be found in one of the successful German world histories of the nineteenth century, the *Allgemeine Weltgeschichte* (*A General World History*) by Georg Weber. At the end of the foreword to the first edition he wrote:

This idea of German superiority is also to be found in one of the successful German world histories of the nineteenth century, the Allgemeine Weltgeschichte (A General World History) by Georg Weber.

[T]he German people more than any other is called to give world history its real shape. Its position in the center of Europe, its aspiration for universal education, its inborn cosmopolitan tendency, which applies the standard of humanity, justice, and philanthropy to the foreigner and the enemy, seems to enable the Germans to act as the guardians and managers of the treasures of history.

Leafing through the many volumes (15 in the second edition, published 1882–1890), one sees that only the first volume is devoted to non-European peoples, actually ancient China, Egypt, India, Mesopotamia, and the Hebrews. Then the path of world history goes continuously and

exclusively through Europe, from ancient Greece to Rome to the Middle Ages and so on to the present. Only the Arabs, with the development of Islam, and the Ottoman empire deserve attention because of their involvement with European history. The Aztecs and the Incas get about five pages. The rest of the world is thus only taken into consideration when it comes in touch with European history. This Eurocentric vision of world history also inspired the 9-volume *Weltgeschichte* (*World History*, 1881–1888) by the most important German historian of the century, Leopold von Ranke, who even ignored China and India in the first volume. In fact, he thought that they and their historical records could be ignored, as he asserted in one of his lectures:

India and China claim to have a great antiquity and their chronology goes far back in time. But not even the most skilled chronologists can find their bearings. Their antiquity is mythical. Their state is rather part of natural history.

The idea of European superiority was developed into the idea of a spiritual historical uniqueness by the German philosopher Ernst Troeltsch. He denied the existence of humanity “as single historical agent,” and asserted that only Europeans had developed a historical consciousness; as a consequence, only a “world history of Europeanness” can be written.

Other successful world histories of the first half of the twentieth century, such as the *Weltgeschichte* edited by Julius von Pflugk-Harttung (1907–1926) and the *Propyläen-Weltgeschichte* edited by Walter Goetz (1929–1933), followed this Eurocentric pattern. But it was nevertheless not unchallenged. In an explicit criticism of Ranke, Hans Ferdinand Helmolt edited between 1899 and 1907 a collective *Weltgeschichte* in nine volumes in which non-European history had a great place and that significantly began with paleontology and prehistory, new sciences generally ignored by historians. He followed a geographic instead of chronological pattern, starting from America and going west until covering all the world.

World History Today

Eurocentrism began a slow decline in the aftermath of the Second World War along with a crisis faced by those teaching nationalistic history, which was rejected in some circles for its perceived warmongering characteristics. With the aim of promoting peace through education, the United Nations Educational, Scientific and Cultural Organization (UNESCO) established among its first goals in 1947 “the publication of a history text-book of world civilization, which would constitute a basis for history-teaching in each country.” In this context a general history of humanity was launched, focusing on science and culture and emphasizing “the interdependence of peoples and cultures and of their contributions . . . to the common heritage.” This *History of Mankind: Cultural and Scientific Development* was published in six volumes between 1963 and 1969. Chronologically organized, it succeeded in giving

a parallel vision of all the parts of the world. In 1978 UNESCO launched an updated project, which has been published since 1994 with the title *History of Humanity*.

In the United States, many historians started working on a new vision of world history. In 1963 William H. McNeill published *The Rise of the West: A History of the Human Community*, one of the most prominent works in the field. Leften S. Stavrianos devoted himself in the 1950s and 1960s to a campaign in favor of the teaching of world history both in the schools and at the college level. In a speech given in 1968 at the annual meeting of the American Historical Association, he stated that history teaching in the United States, which focused on Western civilization, was unfit to promote an understanding of the rapidly changing world and led to a widespread disinterest in this discipline. He added also another criticism to this white Anglo-Saxon Protestant (WASP) vision of history: it did not give space to African Americans and other minorities who now demanded recognition. Thus, Stavrianos singled out two main issues, which are still today at the core of debates about the necessity of overcoming ethnocentrism in history teaching. Despite Stavrianos's engagement, world history did not penetrate most U.S. school systems because of cultural resistance until the problem broke out with the new *National Standards* for history in the mid-1990s. After a long and harsh struggle on cultural and political levels, world history has finally entered U.S. schools and colleges, supported by the achievements of scholarship, which is signified by the establishment of the World History Association in 1982. Europe is, on the contrary, behind the United States in both world history scholarship and teaching. Since the end of the Second World War, in fact, European historians are mostly concerned with overcoming the previous nationalisms through a European vision of history, and at the school level one can even notice in recent years in some European states a revival of national identities. It is significant that in 2001 the attempt to introduce world history in the Italian school system was violently criticized and eventually successfully defeated by politicians and historians as a betrayal of Italian and European identity.

In the early years of the twentieth century, world history was taught as a series of national histories, beginning with Mesopotamia, traveling to Egypt, then to Crete and Greece, thence continuing through Rome toward modern Europe, with little emphasis on the connections. From the second half of the twentieth century, educators in the United States have worked to transmit a greater understanding of the world in which we all live. In the United States, as elsewhere, there is a tension between cultural chauvinism and the desire to fully participate in the global economic systems. In her essay below, Margaret Favretti traces the growth of modern world history courses in public schools. Margaret Favretti, who has received national recognition and honors for teaching in secondary schools—including the 21st Century Northeast Regional Teacher of the Year award in 1995 and the World History Association Teaching Prize, 2006—looks at both the past and the future of world history as taught in the nation’s secondary schools.

—Carolyn Neel

Teaching World History in Secondary Schools

Margaret Favretti

World history came to U.S. secondary schools in waves, beginning in the early parts of the twentieth century. For most of the nineteenth century, the United States was engaged in its own epic efforts to define itself as a commercial-federal-constitutional nation-state, expanding its continental borders, searching for its own distinctive cultural identity, protecting its trade in global systems, and struggling to determine the proper relations between states and the federal government as well as defining individual rights. Not surprisingly, history taught in secondary schools supported these efforts, focusing on those (mainly European) historical moments and trends that had shaped the political and social values and attitudes in the U.S.

As the world emerged from World War I, the “Great War,” historians began to put the years leading up to it into perspective. What they noted was that imperialism and its parallel developments in industrialization, more rapid and effective communication and transportation of goods and ideas, and widespread migration had all contributed to a world where nation-state boundaries seemed perforated by economic, technological, demographic, and cultural shifts, to say little of the supra-national effects of pathogens such as the avian influenza pandemic of 1918. The causes of the war itself seemed to call into question the long-term stability of the nation-state. And during the war, European armies were manned by Africans, Australians, and New Zealanders gathered in Egypt to prepare for a battle against Turks, and Japanese sailors navigated the Mediterranean. The increasingly multicultural nature of many countries was brought to the forefront of the world’s consciousness through wartime efforts to create lasting peace. By attempting to redraw boundaries according to nationality or by ignoring nationality when imposing old colonial boundaries through Versailles Treaty exchanges of

(Lucien Aigner/Corbis)

territory or League of Nations mandates, anticolonial efforts organized and saw some success after the war. Some historians, such as Arnold Toynbee and Oswald Spengler, began to rethink the way history looked and to present the idea of a world history that would look for supranational patterns of human development.¹

In the United States, however, not many secondary schools responded by adopting the new approach. Instead, the United States was just beginning to reap the benefits of its new muscular nation-state. At the same time, the United States was acknowledging its diversity by imposing the first widespread immigration restrictions, and society emphasized assimilation of immigrant cultures to a dominant American culture. The school curricula generally assisted by offering a U.S. first-and-foremost curriculum, which mainly continued the earlier trend of supporting nation-state histories, particularly if they led to important characteristics found in the United States. This meant focusing on U.S. history in several grades, supported by European history or Western civilization in a few other grades. When other societies were studied at all, it was usually to show that they were somehow lacking, or ended

up showing that while different cultures might be exotic or intriguing, they did not really change very much, and thus these studies were not usually called “history.”

The relatively narrow focus of these secondary school curricula also influenced the way that the courses were taught and the way that students were taught to “do”

A great reliance on primary evidence grew throughout the decades, and classrooms became filled with primary source readers to support the narrative textbook.

history. A great reliance on primary evidence grew throughout the decades, and classrooms became filled with primary source readers to support the narrative textbook. All of the documents were translated

(usually from European languages) into English, and many were selected for their “social values” that might encourage good national citizenship among young Americans. If more sophisticated students wished to read the documents in their original translation, they need only turn to their foreign-language instructors, whose curricula stuck pretty faithfully to the European languages. Reading documents from various societies outside of the European/American ecumene would have proven difficult for a typical high school student, who would not only have had trouble finding documents in translation but also would not have had access to language programs geared toward non-European languages. The result was that the primary evidence read by most high school students presented various perspectives resting comfortably within a “Western” point of view.

In the 1960s, cultural upheavals in Europe and the United States led to the rapid inclusion of the “peoples without history” into area studies, or global studies courses, in secondary schools. By the late 1970s, most schools had such an approach. For example, U.S. history courses began to look at native peoples in the Americas prior to European contact and to consider native perspectives on Europeans. Imperialism became less a study of various perspectives on the topic within the colonial powers and instead increasingly included colonial points of view and the impact of colonization on the colonized. Their active efforts to resist its negative pressures were portrayed more frequently as heroic. At the same time, a revitalized study of peoples “on the margins,” including women’s studies, African American studies, and so on, eventually led to looking at other liminal groups, such as nomads and traders, who frequently inhabit a transnational world.

For many historians, the logical next step, particularly after area studies researchers had developed regional or area strands of primary evidence, was to figure out how they were connected. Some researchers began looking for ways to reliably compare and contrast societies and their changes over time. Others began looking for recurring patterns in human experience across time and place. Still others found that the world’s history might fall into exchanges of goods and ideas within and among overlapping systems. Some found that looking at supranational themes such as disease, animals, migrations, technology, food commodities, and so on might open up still more ways of looking at the world. Taken together, these various approaches might be called the “new” world history. Many researchers were excited by the new approaches. They began sharing their thoughts and discoveries with their students. But the field was still very small, and many professors and institutions resisted it because it did not fit easily into the already established disciplines and departments laid out on college campuses. Further, it called on people to use more unfamiliar rules for research and interpretation. Yet today, some form of world history is called for in some part of a K-12 history curriculum by every state in the United States. It is now what most secondary educators expect to appear in a full history curriculum. The fastest-growing offering of the College Board is the AP World History course. As discussed below, each year, the number of students sitting for the exam increases dramatically.

So how did a small but committed group of scholars succeed in moving secondary education toward the new world history? In spite of all of the social and political changes in the world and in spite of the new developments in world history research, secondary education might have lagged far behind if not for the efforts of several individuals and institutions. One of the best ways to facilitate the spread of new research into secondary classrooms is to find people who cross over. Many high school teachers interested in scholarly research join in the research discussions and in the professional organizations of historians, and interested postsecondary educators participate in collaborations with secondary educators to help keep classroom instruction up to date. World history followed this pattern.

In the late 1970s, the Air Force Academy began teaching world history to its cadets. It made sense to the history department chair Carl Redell that academy students trained to circle the world every few days and to “win the hearts and minds” of the people they encountered would and should approach the world with a new point of view. He made contact with some of the other founders of the field and invited them to speak at the academy. In 1982 the Air Force Academy hosted the first of many efforts aimed at establishing collaboration among university researchers in world history and secondary educators, a conference cosponsored by the American Historical Association (AHA), the organization whose members are all professional historians, almost entirely at universities, public history sites, or secondary schools. The conference was a bigger success than expected, and two important outcomes emerged for world history in secondary schools. First, a group of historians—Kevin Reilly (who was representing the AHA), Ross Dunn, Craig Lockard, Marty Yanuck, and Jerry Bentley—founded the World History Association (WHA), a professional organization that would become a model of collaboration between postsecondary and secondary educators. Second, area high school teachers Heidi Roupp and Marilyn Hitchens joined Redell in the Rocky Mountain World History Association, which would eventually become the first regional affiliate of the WHA and would influence the collaborative direction of the WHA as a whole. In fact, the next year saw the WHA approve its constitution, which guaranteed not only that secondary educators could become members of the organization but also that they could hold leadership positions. This made the WHA unique among the professional historical associations and demonstrated its commitment to bringing the new world history into secondary schools.

The late 1980s and early 1990s saw rapid growth in the development of world history for secondary schools, as several models of collaboration helped to bring the new scholarship into classrooms, mainly through the voluntary professional development of teachers. As teachers tried to respond to the changing world, in which telecommunications and globalization made immediate communication and exchange of goods and ideas a common way of life, they wondered how to shift from curricula that emphasized European and American history and non-Western culture studies to one that provided for a more logical world history, while their own background had been in U.S. and European or

area studies. Teachers requested professional development. The new organizations sponsored a series of conferences and a journal, the *World History Bulletin*, with a special section on teaching. New collaborative groups were established, one in Philadelphia through Temple University (Howard Spodek) and the National Endowment for the Humanities (NEH); and another, the Woodrow Wilson Institutes, set up by the Woodrow Wilson National Fellowship Foundation to provide a creative environment for selected teachers to generate working models for world history curricula. The challenge for most teachers was making the shift from their own training, usually in European or American history, to thinking about world history. Additionally, the new world history was a field still emerging and was still so big that teachers would have to make tough choices about what concepts to emphasize and what to leave out. Over the course of three summers, the Woodrow Wilson Institutes tried to resolve this dilemma by creating model curriculum units and teacher-training approaches for the premodern era before 1450 CE, the years 1450–1750, and the modern era. The “Woody” teachers then became a strong nucleus of teacher-trainers who traveled around the country training teachers to teach world history. Many of these Woodrow Wilson Institute’s teachers and professors participated in the NEH-funded efforts of the National Center for History in the Schools to devise curriculum standards in world and U.S. history for grades K–12.

The challenge for most teachers was making the shift from their own training, usually in European or American history, to thinking about world history.

Several states had already begun investigating state standards for world history on their own, without adequate academic leadership, and had produced some bizarre drafts. The National Center for History in the Schools, under the guidance of Gary Nash and Charlotte Crabtree, wanted to provide a sound academic and pedagogical guide for those efforts as well as a responsible foundation for teachers and schools as they began devising their own world history curricula. The ensuing “culture wars” (mainly a political attack against the U.S. Standards on the basis of Lynne Cheney’s charge that they presented a “grim and gloomy” view of U.S. triumphs) discouraged some political officials from officially adopting the standards but actually speeded up the dissemination of the standards among the schools. The media attention encouraged large numbers of educators to read the standards, in which they found broad-based support for teaching world history and a sound approach for organizing their world history courses.

Further support and professional development grew exponentially after Heidi Roupp received an NEH grant in 1999 to sponsor 11 summer institutes (and one on-line institute) to train world history teachers. The first meeting involved a train-the-trainers session that prepared experienced world history educators at various levels to run the collaborative two-week seminars. The summers have been filled with institutes ever since, especially since the College Board initiated its Advanced Placement World History course and examination.

Students in an advanced placement history class in Laredo, Texas, 2009. (Bob Daemmrich/The Image Works)

The College Board began discussions about the advisability of offering Advanced Placement World History in 1999. The leadership of the members of the College Board History Academic Advisory Committee was instrumental in furthering the cause. There were internal concerns about whether or not world history was an accepted undergraduate course, whether or not an AP version could be taught, and whether there were enough teachers to teach it. Choosing to lead rather than follow, the College Board approved an AP course in 2000, and the course outline was prepared immediately by scholars and teachers on the test development committee, aided later on by the Academic Advisory group. In 2006, the fifth year of the administration of the AP exam, about 85,000 students took the test, making it the most rapidly growing course in the history of AP. The number of students taking the AP World History examination had skyrocketed to around 145,000 in 2009 and was up to 168,000 in 2010.

Today, every state in the United States makes at least some provision for world history in its standards. Not all of them give it strong secondary-school attention, but it is a part of what most high school students can now expect from their curricula. The story of how world history came to be taught in secondary schools is largely the story of how academic scholarship can move into secondary classrooms through professional development and collaboration among secondary and postsecondary educators. The readiness of our students and their communities to learn world history reflects the nature of our interconnected world.

SECTION 3

The Overarching Issues, Seeing the Big Picture

Introduction

Carolyn Neel

History, the story of the human past, is vast. In its totality, it is too big to see, much less to learn. We normally separate “histories” into manageable chunks, but in order to understand human history—the story of our past as a species living on planet earth—we have to assemble those bits and prepare summaries in broad strokes. In this section, we attempt to combine the many pieces into a broad narrative.

The first four of these essays focus on humanity’s place in the natural world. We begin with Dr. J. R. McNeill’s insightful essay on humans and the natural world; although some would like to think that people are outside of (or, perhaps, above) the natural world, there is great risk in forgetting our own natural place. The second essay, by a prominent sociologist, Dr. Douglas Massey, is a digest of human history (so far) in approximately 13,000 words, which provides a rich and exciting overview; a serious, sophisticated study of the development of human societies. From works of this nature, readers gain a solid feel for our past as well as a sense of the historian’s mission. In their essay on regional geography, cultural geographers Dr. Donald Rallis and Dr. Melina Patterson challenge our perceptions of regions as “natural” as they consider the role of human perception and cultural worldview in shaping our beliefs about the earth’s landmasses. We continue the theme of humans as geographical actors in “Migration in Human History,” by Dr. Patrick Manning. Wonderfully adapted for mobility, humans spread from Africa and settled on every significant landmass except Antarctica.

The rest of these essays address human cultural adaptation, such as the development of language. As we spread across the earth, humans developed means of communication, as Dr. Harald Haarmann writes, and took note of the mysteries of the surrounding world, a topic also discussed by Dr. Todd Duncan in “Cosmology and Religion: The Human Quest for Meaning.” The last essays focus on cultural and economic adaptation. Technology, arguably the means through which humans came to dominate the planet, merits two essays; the first, “Humans, the Tool Makers,” by Dr. Marvin Kay, addresses the principles of tool making and

reflects on the role of primitive tool-making activities. Dr. William E. Burns, in “Technology in World History,” considers technological development’s place in creating the modern world. About 12,000 years ago or so, tool making led to an intense effort in some areas to shape and control living conditions. These efforts were gradual and often erratic or fitful, and, as Dr. Kevin M. McGeough discusses, agriculture was not an unmitigated benefit to any of the early farming societies. Nevertheless, agriculture did make large-scale urbanization possible, and Dr. Howard Spodek’s entry, appropriately called “Urbanization,” investigates the phenomenon. Like dominoes falling, we turn to “The Evolution of Complex Political Organizations,” by Dr. Paul Roscoe, thence to “Industrialization in World History,” by Dr. Carolyn Neel, and “Globalization in World History,” by Dr. Erik Gilbert.

We do, of course, encourage readers to pursue their interests, but reading these essays in order illustrates the swift acceleration of historical changes. For thousands of years, the lives of people on earth changed little from one generation to another, as hunter/gatherers formed bands, perfected their tools, and made gradual technological and cultural innovations (such as using fire and making warm coverings) that allowed them to live in climates which would otherwise have been uninhabitable. Then, the economic changes introduced by the adoption of agriculture—such as urbanization, political organization, and industrialization—set people on a different path. For at least the past century, people—often novelists, poets, or artists (such as Mary Shelley in her 1818 novel *Frankenstein*, or Edvard Munch in his painting *The Scream*)—have expressed qualms. Nevertheless, there can be little doubt that 100 years from now, a new edition of this volume would require several more essays.

Humans are a part of the natural world—a fact we overlook at great cost. In the essay below, Dr. McNeill considers the ways in which humans expanded their ecological range, at first using technologies such as fire, agriculture, animal husbandry, etc. While nineteenth-century historians focused on rulers and warfare, revolutions and statecraft, McNeill's essay shows another perspective through environmental history, which considers the larger interaction between humans and nature—whether in the form of microbes, wetlands, or the atmosphere itself.

—Carolyn Neel and Fred Nadis

Humans and the Natural World: The Long View

J. R. McNeill

For most of our career we, like our hominid ancestors, lived in small bands but roamed large territories. We had little impact on the earth, but the earth had much impact upon us. Then our ancestors, whether human or hominid, learned to harness fire and, later, to make it. This was one of history's great turning points, although we don't know when it happened. Informed guesses suggest maybe half a million years ago. Fire allowed our ancestors to shape landscapes through burning of vegetation. It allowed them to turn forest into grassland and to favor the big herbivores that were easiest to hunt; it proved useful in keeping big carnivores at bay, improving our ancestors' survival chances; and it permitted cooking, which widened the range of possible foods we can eat, improving nutrition. Fire changed our ancestors' place in nature and reduced the chance that they might go extinct, as other branches of our genus did.

Another turning point in the human relationship with nature came with the acquisition of language. Again, we do not know when it happened (maybe around 150,000 years ago), but with it hunters could plan their attacks in detail, foragers could coordinate their efforts, and learning from experiences became faster, easier, and more cumulative. This made us fully human and far more formidable than other creatures of the biosphere.

In Africa our ancestors had coevolved over many millennia with various microbes that fed upon them and with animal prey upon which they fed. This checked their population. But about 100,000 years ago some of them strolled out of Africa into Asia, and by exiting their long-term home they stole a march on the rest of nature. They left some pathogens and parasites behind. They also walked into landscapes brimming with native animals that had never been stalked by projectile-throwing upright apes capable of coordinating hunting efforts through language. They were an exotic invasive species, and as invasive species often do, they flourished in these new landscapes, reproducing prolifically and causing ecological havoc.

Big mammals suffered most. Soon after people arrived in Australia (maybe 60,000 years ago), many species of large mammals went extinct. The same thing happened in the Americas (roughly 14,000 years ago). Similar extinctions also occurred when people first settled the previously uninhabited islands of Madagascar (about 2,000 years ago) and New Zealand (about 1,000 years ago). Sometimes these pulses of extinction are attributed to other things, such as climate changes. Probably both human predation and climate change were often involved, in different proportions in different settings, although climate change likely had nothing to do with the extinctions on Madagascar or in New Zealand.

About 10,000–11,000 years ago, perhaps spurred by climate change, people began to produce food rather than merely hunting and gathering. This transition has been justly regarded as another great turning point, apparently began in the foothills of the Zagros and Taurus mountains in the Middle East. However, had it happened earlier in tropical rain forests or along coastlines now submerged (sea level was about 330 feet [100 meters] lower 10,000 years ago), we probably would not know. It seems to have happened independently at least five or seven times, perhaps more, all between 11,000 and 4,000 years ago, and to have diffused from each point of origin.¹ Humankind now acquired an enormous incentive to sculpt landscapes into fields and gardens, to permit only certain species to grow, and to work hard to extirpate others, now understood as weeds and vermin. Farming meant much denser and more sedentary human populations. It involved the gradual creation of new domesticated breeds of plants and animals. When people learned to irrigate crops, it came to involve a new connection to fresh water and amounted to a thorough revolution in the human environment and the human relationship to nature.

As human populations grew in size, individuals shrank in stature. On average early farmers were shorter than their foraging ancestors. These farmers ate less varied diets and much less animal protein than did nonfarmers and suffered more often from vitamin-deficiency diseases.

Those who did not move around lived among their own wastes and consequently suffered from gastrointestinal diseases. Their lives, like their bodies, were shorter than those of hunters and foragers. But farmers reproduced faster than any other human populations.² When farmers came to live cheek by jowl with their livestock (mainly in Eurasia), their health got worse still. Some of the diseases that infected livestock evolved into human diseases such as measles, tuberculosis, influenza, and smallpox.

However, to some extent the presence of livestock improved the human diet, especially where dairy cattle could be raised (and adult human populations developed the capacity to digest milk).

A new stage in world environmental history began about 5,500 years ago with the first cities. Urban populations generally could not reproduce fast enough to offset their high mortality, and cities survived

As human populations grew in size, individuals shrank in stature. On average early farmers were shorter than their foraging ancestors. These farmers ate less varied diets and much less animal protein than did nonfarmers and suffered more often from vitamin-deficiency diseases.

only through constant influx from surrounding villages. Cities were demographic black holes until improvements in sanitation and disease control about 100–150 years ago. The surplus of deaths over births in London around 1750 was enough to cancel out half the natural increase of England.³

City life also altered agriculture. In village settings, soil nutrients cycled through plants and human bodies and eventually returned to the earth. Among urban populations, soil nutrients accumulated in cities after shorter or longer stays in human bodies and tissues. Carrying human excrement (“night soil”) from cities to the fields compensated somewhat for the long-term drawdown of soil nutrients. But the distance over which such measures were practical was much shorter than that over which farmers sent food to cities. So, over time cities reduced the fertility of the fields that supplied them, especially cities perched on riverbanks or seacoasts, because their wastes were often dumped into the water and thus their nitrogen and phosphorus was forever lost to farmers’ fields. The only way to counteract this nutrient loss was to use manure from animals that grazed in forests or meadows. The animals imported nutrients to farmers’ fields. Hence, as a Polish nobleman of the sixteenth century pithily put it, “manure is worth more than a man with a doctorate.”⁴

According to a controversial new hypothesis, early agriculture also affected climate. Some 8,000 years ago, it seems that the concentration of carbon dioxide (CO₂, the main greenhouse gas) in the earth’s atmosphere began to climb slowly. This came after about 2,000 years of declining CO₂ and when, according to climate models based on earlier alternations of ice ages and interglacials, the CO₂ levels should have continued to fall. How could this happen? Maybe because agriculture spread far and wide. Farmers cut and burned enough forest to send about 200 billion tons of CO₂ into the atmosphere. This may have forestalled the next ice age. The advent of irrigated rice farming, around 5,000 years ago, put additional methane into the atmosphere. Methane is also a greenhouse gas, and its rising concentrations over the past five millennia may have helped warm the earth. If this hypothesis is correct, human behavior has been affecting climate in significant ways for 8,000 years rather than merely in the last two centuries.⁵

Agriculture remained the most important way in which humankind affected the environment for millennia. Agrarian societies snatched the most fertile and well-watered lands, pushing pastoralists and hunter-foragers to the margins. Slowly, inexorably, human numbers grew, and more and more land became field, pasture, and garden. Agro-ecosystems spread. Domesticated animal populations flourished. Forest and other wild lands shrank back.

This slow frontier process is the main theme of world environmental history from 8,000 years ago until modern times. John Iliffe made it the central theme of African history in his survey *Africans: The History of a Continent*, in which Africans are cast as world history’s frontier farmers par excellence, struggling to carve their fields from the forests and keep wild animals at bay. Mark Elvin presented Chinese history in a similar light, an epic of frontier expansion of Chinese styles of agriculture

Agricultural terraces built by the Inca at Moray, near Cuzco, Peru. Crops including wheat and quinoa were grown on the terraces, which were equipped with built-in irrigation systems. (Robert Weller)

slowly taking over more and more land, assimilating or expelling other peoples, and all the while chiseling the earth into paddies and plots. Elvin assigns the Chinese state a key role in promoting this frontier process, which is quite different from the African story. But as ecological phenomena, the general pattern is quite similar.⁶

Epic agricultural expansions also characterize the history of the Indian and European subcontinents and the Americas as well. Where populations became large and dense, this resulted from successful agriculture. Large and dense populations (or at least the poorer people within them) normally felt a need to migrate, to expand, or to set up new colonies. Wherever they could drive off, kill, or absorb hunter-foragers and pastoralists, they usually did so. Thus, eventually agriculture covered one-third of the earth's land surface, arguably the largest environmental impact (such things cannot be reliably quantified) of the human race.

Humans also affected environments by moving plants, animals, and microbes around both intentionally and accidentally, a process often called ecological exchange. Wheat, for example, somehow got from the site of its original domestication, in southwestern Asia, to China by 1500 BCE. When and where conditions (e.g., peace) promoted travel and trade, the spread of crops and presumably also

weeds and pests accelerated. In the era of the Han and Roman empires (ca. 200 BCE to 200 CE), for example, China and the Mediterranean world exchanged numerous useful plants and animals: China acquired grapes, peas, alfalfa, sesame, camels, and donkeys. Sea transport encouraged ecological exchange over enormous distances. Austronesians carried bananas from Southeast Asia to eastern Africa, improving the prospects of farming in the moist forest regions around Africa's great lakes. Polynesian seafarers brought a suite of crops and a few animals throughout the South Pacific. All of this furthered the frontier epics of agricultural expansion; it also promoted a slow process of ecological homogenization whereby humankind altered ecosystems so as to raise a small handful of rewarding crops.⁷

A famous pulse of ecological exchange followed upon Columbus's voyage from Spain to the Americas in 1492. After the original human invasion of the Americas toward the end of the last Ice Age, very little interaction took place between the Americas and the rest of the world. The history of the Western and Eastern Hemispheres, although showing some parallels, remained separate. But the biota of the two hemispheres mingled after 1492, with tumultuous results. Eurasian and African diseases ran rampant among Amerindian peoples, reducing populations by 50–90 percent between 1500 and 1650. Eurasian livestock colonized the grasslands and some of the forests of the Americas. Wheat, barley,

oats, African rice, and a few other crops proved useful in the Americas. Going the other way, maize and potatoes spread widely in Eurasia and (maize, anyway) in Africa. How different would Irish history be without the potato or Argentina's history without wheat and cattle?⁸

The economic globalization that followed in the wake of Columbus and other mariners of the fifteenth and sixteenth centuries brought environmental changes beyond the flurry of ecological exchange. Chinese demand for silver drove a global mining boom, most rewarding in Japan, Mexico, and the Andes. Mining changed the face of the earth and spurred deforestation. In the case of silver, processing ores, which was most efficiently done with mercury, brought lethal pollution. Fur and hide markets animated a global hunt for beaver, seals, and deer, reshuffling ecosystems in North America, for example, where before 1800 beaver had played a key role in sculpting landscapes (and water-scapes). Markets for sugar inspired the creation of a plantation complex, first around Mediterranean shores and then on Atlantic islands and, on the largest scale, in northeastern Brazil and the Caribbean lowlands. Sugar brought deforestation, soil nutrient depletion, and biodiversity loss.⁹ Ongoing economic and ecological globalization lurched into a higher gear around 1500 and is still in motion. Overlaid upon it, since about 1800, is the emergence of high-energy society, based on fossil fuels.

From an economic and social point of view, the Industrial Revolution is justly regarded as a world-historical turning point. It is even more so from the point of view of environmental history. Before fossil fuels, people had great difficulty deploying enough energy to get work done. Human muscle power, supplemented in cases with animal muscle and, in a few select locations, wind or waterpower was the main energy source. This was a great constraint on how much work could be done and therefore how much wealth might be created. It also accounted for the popularity of slavery in the preindustrial era: there was no more efficient way to get big things done than to amass human muscle.

Fossil fuels opened a new era. They represent a subsidy from the geologic past, bestowed upon recent generations. Their ecological effects were enormous. First, fossil fuels made possible the big cities of the modern era. They allowed food to be brought in fast enough to keep millions of people alive. They made the factory labor of the toiling masses far more rewarding so that factory owners, and eventually laborers, could afford cotton, tea, sugar, and other products from far continents, changing the landscapes of India, Egypt, and the Caribbean.

Fossil fuels were a dirty innovation. The first industrial cities in Britain were horribly polluted as a result of the burning of coal.¹⁰ Mining coal, like drilling oil, was a messy business itself. Burning it was messier still. In nineteenth-century cities such as Manchester, Pittsburgh, or Osaka, coal smoke blocked out the sun, soot soiled every surface, and

Markets for sugar inspired the creation of a plantation complex, first around Mediterranean shores and then on Atlantic islands and, on the largest scale, in northeastern Brazil and the Caribbean lowlands. Sugar brought deforestation, soil nutrient depletion, and biodiversity loss.

airborne particles invaded enough lungs to help kill hundreds of thousands through respiratory infections.

Oil, the main fossil fuel globally by the 1950s, made energy cheaper still. Cheap oil made it economical to slice the top off mountains in search of a few specks of gold. After 1960, cheap oil (and chain saws) brought a surge of cutting and burning in the world's tropical rain forests, a major ecological change of our times. Cheap oil made the fertilizers and pesticides of modern agriculture feasible as well as the agricultural machinery and transport networks that help bring food from fields to tables almost everywhere. Without cheap oil, agricultural yields would be roughly half what they are, and the quadrupling of human population since 1910 could not have occurred. Of all the causes of environmental perturbation in the last century, cheap energy tops the list.

Since 1950 we have lived in an age of extreme ecological turbulence. The earth's history includes yet more turbulent episodes but none brought on by humankind. Awareness of our role as disturbers of the biosphere sparked the movements known as environmentalism, recently part of cultural, intellectual, and political scenes almost everywhere around the world. To date, environmentalism and associated new governmental regulations, market incentives, and greener technologies have dialed back the ecological turbulence somewhat but made no fundamental impact on the human relationship to the biosphere. The momentum of history remains too strong for now. For the future, as usual, only time will tell.

In the essay below, Dr. Massey presents the grand global view of human history. World history courses, in universities as well as high schools, are taught in manageable but rather detailed chronological chunks, sometimes further separated into geographical divisions. Although students usually gain an understanding of the various segments—the Neolithic changes in the Fertile Crescent, for instance—it is generally difficult for readers to get a broad sense of the overall developments and changes in human life. Many world history courses, like national and regional histories, tend to focus on contrasts, emphasizing the ways in which a specific culture is unique. This focus on differences, while valuable, tends to obstruct the broad view and can distort our understanding by giving dissimilarities undue weight. Dr. Massey very effectively traces the similarities between societies, the distinctively human characteristics that find expression across the world. In so doing, Massey leads us through the grand narrative of human life on earth so far. The 10,000-yard view of the mosaic illustrates human commonalities and allows us to get a feel for the history of human beings as a family. It's a good starting place for any world history course. It is also a good reminder for all of us of our own place in history. In a recent article, David Christian remarked on the importance of scale as we study history, using maps—global, regional, city, etc.—as an analogy.* This is history at its grandest scale, the global view, temporally as well as geographically.

A Brief History of Human Society

Douglas S. Massey

Before the end of the second decade of the twenty-first century, two momentous events will have occurred. Somewhere around 2007, humanity crossed a demographic Rubicon: for the first time, more than half of all human beings will live in cities. From that point on, the bulk of population growth will occur in urban areas, thus guaranteeing that the human future will unfold in cities. Shortly thereafter, surely during the second decade of the twenty-first century, the last foraging societies will cease to exist, ending 6 million years of dedication to what Jared Diamond called "the most successful and long-persistent lifestyle in the career of our species."¹

As organisms, human beings evolved within the context of small social groups. In many ways, we are more adapted to life in small groups than to survival within any particular physical habitat. The natural forces that bind us together into cohesive communities are very old and predate our much-vaunted cognitive capacities for language and rational thought. Emotional bonds linking hominids together within stable social structures existed long before human beings were able to undertake any rational consideration of the costs and benefits of sociality. If we are to comprehend our place in the contemporary postmodern, postindustrial landscape, we must return to our emotional origins in the class of primates known as hominids and to the foraging societies they inhabited.

Foraging as a Way of Life

Humans are the last survivors of a host of bipedal primates, known as hominids, who once walked the earth. The evolutionary path from the first biped to ourselves resembles not so much a tree as a bush, with many branches drifting off to extinction and others continuing toward the present. Considering this shrub from its origins to the dawn of urban civilization and paying attention to the fundamentals of population, community, technology, subsistence, and culture, one may identify four basic eras of societal development.

Pre-Habiline Society

Recent archaeological finds have pushed the origins of the hominid line back to around 6 million years ago, when *Ardepithecus ramidus* and later *Australopithecus africanus* descended from the trees to spend their days walking upright, thus enabling them to exploit an emerging ecology of mixed forest and grassland.² Our earliest ancestors were small, averaging just slightly less than 5 feet (1.5 meters) in height and maybe about 155 pounds (70 kilograms) in weight but with a pronounced sexual dimorphism that left males 60 percent larger than females. Among primates, such high dimorphism is associated with a pattern of female out-marriage into a group composed of a dominant male plus subordinates, consorting females, offspring, parents, and siblings.³ As such, their way of life was probably similar to that of modern-day chimpanzees, which is organized around foraging, scavenging, and the occasional hunting of small prey.⁴ There is no evidence that the early *Australopithecines* manufactured permanent tools; hence, their society is labeled

The teeth of the Australopithecines were large, their jaws were adapted for crushing, and their guts were capacious, suggesting a diet centered on vegetable matter.

pre-habiline (pre-tool-using). Like modern chimps, they probably modified perishable materials and wielded unworked stones for a variety of purposes. The teeth of the *Australopithecines* were large, their jaws were adapted for crushing, and their guts were capacious, suggesting a diet centered on vegetable matter. Some have argued that the *Australopithecines* descended from trees precisely in order to exploit new ground-based food sources (protein-rich roots and tubers) that were becoming available on the expanding savannas.⁵

Groups of early hominids, like modern chimps, were probably loosely structured socially.⁶ Chimpanzee communities are held together by emotional bonds between individuals differentiated by sex, age, and rank in a dominance hierarchy. Within groups, rather strong ties exist between mothers and children, and these may persist even after the latter are grown, especially for male offspring; weaker ties exist between adult males; and ties between other community members are generally weak or absent. Females transfer out of the group at puberty, preventing the formation of strong structures based on intergenerational matrilineal lines of related females and fostering male-dominance hierarchies. Among apes and our last common ancestor, social structure was fluid, “leaving indi-

viduals at the micro level to seek out their own supportive ‘friendships’ that reflect personal likes and dislikes” that creates an overall sense of community at the macrolevel.⁷

Emotional bonds of kinship and friendship are maintained by mutual grooming, while rank is established by threat displays backed up occasionally by actual force. Social relations are complex, requiring each individual to recognize and form alliances with others. Chimps must cultivate webs of influence and mutual obligation, form coalitions to defeat common adversaries, remember the personal attributes and past behaviors of others, and know of relationships between others.⁸ Studies and field observations show that chimpanzees are self-aware, are able to infer the intentions of others, and are fully capable of social deception and manipulation.⁹ It is quite likely that Australopithecines possessed similar capacities.¹⁰

Compared with modern-day chimps, however, early hominids lived in larger groups. Whereas chimps normally exist in groups of around 50, calculations by Robin I. Dunbar suggest that Australopithecines lived in bands of 60–70 individuals.¹¹ Like chimpanzees, therefore, the earliest hominid species must have possessed a well-developed social intelligence. The number of dyads (mated pairs) among any number (N) of individuals is given by the formula $(N^2 - N)/2$. Whereas chimps (at $N = 50$) must keep track of 1,225 dyadic relationships, Australopithecines (at $N = 65$) had to manage 2,080, which requires more cognitive ability.¹² As a result, the average cranial capacity of Australopithecines, somewhere around 450 cc, is larger than that of chimps, which averages around 400 cc.¹³

The increase in cranial capacity stems from an expansion of the neocortex, the outermost layer of the brain, yielding a higher degree of encephalization.¹⁴ Despite their keen social intelligence, however, there is no evidence that Australopithecines possessed much in the way of what we would call rationality. The frontal, temporal, and parietal lobes of the brain—the loci of abstract reasoning and language—remained relatively undeveloped, and there is little evidence of any asymmetry between the right and left hemispheres, a definitive characteristic of habitual tool manufacture. Expansion occurred mainly in portions of the cortex that dealt with sensory processing and probably involved a rewiring to enable greater cortical control of emotional expression.¹⁵

Like modern chimps, the early Australopithecines could probably solve simple practical problems and learn through observation and imitation, but communication was restricted to vocalizations and gestures. Although modern chimps can be taught 150–200 symbols in the laboratory and can learn to string them together in sets of 2 or 3,¹⁶ they display no awareness of word order, and over millions of years they never evolved the use of symbols themselves.¹⁷ Chimps do not even engage in spontaneous pointing, a behavior evinced by youngest human children.¹⁸

Pre-habiline cognition is associated with what Merlin Donald calls episodic culture, in which perceptions and behaviors flow largely in the present moment.¹⁹ Individuals have memories of concrete past episodes, can recall prior experiences, and can perceive ongoing social situations, but they lack semantic memory and abstract reasoning. Pre-habiline

Table 1. Eras in the evolution of human foraging societies

	Pre-Habiline	Oldawan	Paleolithic	Neolithic
Beginning date	6 million BP	2.5 million BP	1.5 million BP	50,000 BP
Duration	3.5 million yrs	1 million yrs	1.5 million yrs	40,000 yrs
Generations	175,000	50,000	75,000	2,000
Inhabitants	A. Africanus	H. habilis	H. erectus	H. sapiens
Cranial capacity	450 cc	550 cc	1,100–1,400 cc	1,450 cc
Sustenance	Foraging	Foraging	Foraging	Foraging
Tools	Perishable	Crude stone	Refined stone	Flint and bronze
Kind of culture	Episodic	Episodic	Mimetic	Mythic
Settlement type	Mobile camp	Butchering site	Base camp	Village
Community size	~65	~75	~145	~155
Total population	<50,000	<100,000	<1 million	6 million

society and its episodic culture dominated human life for 3.5 million years. During all this time—some 175,000 generations—no stone tools were produced, and hominid life was confined to Africa, yielding a population that numbered only in the thousands or tens of thousands of beings dispersed into small roaming groups.²⁰ The essential features of pre-habiline society are summarized in Table 1, in comparison to its successors.

Oldawan Society

The first revolution in human history occurred with the appearance of stone tools about 2.5 million years ago and was associated with the appearance of a new genus. *Homo habilis* made crude stone artifacts that most of us would not even recognize as tools unless we knew what to look for. Named for the east African gorge where they were first discovered, Oldawan tools are pieces of rock that have been sharpened on one side by flaking to create crude choppers and scrapers. These simple tools are associated with the first evidence of patterned human living in the form of centralized butchering sites, indicating a growing reliance on hunting over gathering.

Although height did not change dramatically, the weight of *Homo habilis* did increase as skeletons grew more robust and cranial capacity rose to an average of around 550 cc,²¹ a 20 percent increase associated with an expansion of group size to 70 or 80 individuals.²² The increase in group size not only required a greater cognitive capacity to monitor the increased number of interpersonal dyads (2,775 at N = 75) but would have also necessitated a concomitant increase in the amount of time spent grooming. Primates cultivate and maintain dyadic bonds through mutual grooming, which causes the release of natural opiates in the brain to promote feelings of well-being and attraction leading to social cohesion.²³

Group size is naturally limited by the amount of time individuals can afford to spend grooming rather than engaging in other essential behaviors such as sleeping, feeding, courting, and mating.²⁴ Across primates, 20 percent seems to represent an upper threshold for time spent grooming. The group size characteristic of *Homo habilis* for the first time pushed grooming time above this threshold, suggesting that other mechanisms must have been coming into play.²⁵ Turner suggests that these mechanisms involved a more complex communication of emotion.²⁶

Beyond increased group size, the existence of stone tools, and a larger brain, little else changed cognitively, culturally, or socially for hominids during the Oldawan period, which lasted around 1 million years, or 50,000 generations. The total human population at the time still numbered in the tens of thousands, all lived in Africa, and there is no evidence of any use of language or symbolic culture (see Table 1). Hominid culture remained episodic, albeit with an increase in social complexity and a concomitant expansion of cranial capacity to handle greater demands on social intelligence.

Paleolithic Society

Somewhere around 1.5 million years ago, the appearance of another species and technology signaled the emergence of a new kind of society. The species was *Homo erectus*, and the technology was the Acheulean tool culture. The progression from *habilis* to *erectus* marked an abrupt and very important shift in human evolution.²⁷ Although upper heights changed relatively little, they became considerably more uniform (4.2 to 4.9 feet [1.3 to 1.5 meters]) as sexual dimorphism was reduced dramatically from a 60 percent male-female differential to one on the order of 15 percent, about the average for modern humans. Anatomically, full shoulder rotation disappeared, indicating a final break from arboreal (tree-living) life, while both teeth and guts grew smaller, suggesting the increasing nutritional importance of meat. With the emergence of *Homo erectus*, we find evidence of the controlled use of fire²⁸ and the creation of seasonal base camps.²⁹ The sharp decrease in sexual dimorphism stemmed not from a reduction in the size of males but instead from an increase in the size of females, thus raising the average height of hominids. The increase in female size was necessary to accommodate the birth of new creatures with large heads and fat brains, for the progression from *Homo habilis* to *erectus* was accompanied by a doubling of cranial capacity into the range of 1,000–1,100 cc. The dome of the cranium rose and the face flattened to accommodate expansion of the frontal, temporal, and parietal lobes of the brain. *Homo erectus* also provides the first evidence of brain laterality—a differentiation in size between right and left brain hemispheres—that is associated with handedness and communicative abilities.³⁰ Rather than the crude chop-pers of the Oldawan culture, the Acheulean tool kit evinced considerable manual dexterity (which goes along with handedness). Tools now consist of symmetrically shaped, carefully worked hand axes, cleavers, and knives with sharper and more effective cutting surfaces.

Skulls of prehistoric primates
(from left: *Homo erectus*, *Homo rudolfensis*, *Homo ergaster*, *Homo habilis*). (Deco)

The decline in sexual dimorphism and the need to care for large-brained children who were helpless in infancy, vulnerable in childhood, and dependent through adolescence produced a radical change in human social structure and mating patterns.³¹ It was probably during this era that the human practice of pair bonding appeared, accompanied by a decline in intermale conflict, the disappearance of rigid dominance

It was probably during this era that the human practice of pair bonding appeared, accompanied by a decline in intermale conflict, the disappearance of rigid dominance hierarchies, and a growing investment by fathers of time and resources in their mates and children.

hierarchies, and a growing investment by fathers of time and resources in their mates and children.³² Male commitment to pair bonding was reinforced (though not guaranteed) by an entirely new reproductive biology in which females were continuously sexually receptive, breasts were enlarged and displayed, and the timing of estrous was hidden. The distinctively human and unprimate practice of copulating in private probably also emerged at this time.

The increase in brain size enabled another expansion in group size to 90–120 individuals, yielding somewhere in the neighborhood of 6,000 dyadic relationships ($N = 110$). Despite greater encephalization, however, evidence suggests that the intelligence of *Homo erectus* was still prelinguistic. It was, however, different from the episodic intelligence that preceded it. The basic cognitive function for *Homo erectus* was mimesis—imitation or mimicry—in which vocalizations, facial expressions, eye movements, body postures, and manual signs were used to communicate and to transmit skills from person to person. The emergence of gestural communication reflected a significant increase in the range and complexity of emotional expression, as the cognitive bases for primary emotions such as fear, anger, disgust, happiness, and sadness were rewired and interconnected via the cortex to produce

new sets of emotions conducive to social cohesion and solidarity, such as shame, guilt, anticipation, and hope.³³

Learned physical abilities were an essential adaptive resource and were passed from generation to generation by demonstration and imitation.³⁴ Although mimetic culture remained concrete, visual, and episode-bound, it nevertheless brought about an increase in the sharing and accumulation of knowledge, yielding a more stable social structure based on ritual and custom that served to heighten the emotional content of social relationships and promote bonding.³⁵ It was during this phase of human social evolution that facial expressions probably attained their current importance as means of signaling emotion.

Patterns of nonverbal facial expression recur across cultures and are interpreted similarly by humans in all societies, suggesting a “hard-wired” ability to read emotions that are displayed on the human face.³⁶ The resulting mimetic culture provided humans with a powerful adaptive tool that enabled them to leave their ancestral homeland for the first time and survive in a wider variety of habitats. Around 1 million years ago, *Homo erectus* moved out of Africa and occupied the southern portions of Asia and Europe, bringing about the first significant growth of the human population.³⁷ Late in the Paleolithic period, around 300,000 years ago, several new species of hominid arrived on the scene to compete with *Homo erectus*, which eventually disappeared. The new species were *Homo heidelbergensis* and the better-known *Homo neanderthalensis*, also known as the Neanderthals.³⁸ The latter approximated modern humans in height but were much heavier and more powerfully built, with thicker bones and a more robust musculature. The size of the cranium also expanded to reach volumes characteristic of our own species, although the physical organization of the brain remained distinct, with smaller and more constricted frontal lobes. Nonetheless, the increase in average cranial capacity to around 1,400 cc enabled group size to expand further, reaching 120–160 individuals and implying a need to manage some 9,730 separate dyadic relationships ($N = 140$).

With groups this large, the maintenance of cohesion could not possibly have relied on mutual grooming, as servicing so many relationships would have required around 40 percent of the group’s entire time to be spent grooming, a percentage that is far too long to be feasible.³⁹ Culture, therefore, must by then have been the central mechanism maintaining social cohesion.

The Neanderthals evinced a more advanced material culture than their hominid predecessors, as indicated by the emergence of a new tool kit, the Mousterian, that consisted of flint or stone blades hafted onto wood or bone handles. These represent the first instance of composite tools, those composed of at least three materials. The new tool kit yielded ten times more cutting edge per kilo of raw material than the former Acheulean technology. With the Neanderthals we also begin to observe stone hearths and postholes, indicating the construction of permanent shelters. We also observe migration and settlement in the colder regions of northern Europe, and numerous bone middens indicate a heavy reliance on hunting. With the emergence of semipermanent settlements of 120–160 persons, social structure probably began to move

beyond small bands differentiated by age and sex to form larger collectives such as kin-based clans.

Neolithic Society

Fully modern human beings emerged in Africa somewhere around 150,000 years ago and rapidly migrated outward to occupy all corners of the globe. *Homo sapiens* reached Europe and Asia around 50,000 before the present (BP), Australia by 40,000 BP, the Arctic by 20,000 BP, the Americas by 10,000 BP, and most of the islands of Polynesia by 2,000 BP.⁴⁰ Whereas the Australopithecines and habilines had remained in Africa for 5 million years without moving and *Homo erectus* and the Neanderthals had not expanded beyond southern Europe and Asia over 1 million years, within the space of just 50,000 years the entire earth was populated fully by *Homo sapiens*. Clearly they must have gained access to some remarkable new survival tools. Demographers estimate that the prehistoric human population had grown to roughly 6 million persons by around 10,000 years ago.⁴¹

In *Homo sapiens*, the brain reached its final size and structure with a full expansion of the frontal lobes that created the potential for a new and revolutionary kind of culture.⁴² The importance of the human brain as an adaptive organ is indicated by the fact that it constitutes 2 percent of body weight but uses 20 percent of the body's total energy.⁴³ Nonetheless, the appearance of anatomically modern human beings was not initially accompanied by dramatic changes in culture.

The crucial period of change seems to be around 50,000 years ago, an era that has variously been called “the great leap forward,”⁴⁴ “the creative revolution,”⁴⁵ and “the symbolic revolution.”⁴⁶ From this point onward, technology undergoes rapid change that is disconnected from further changes in brain size or anatomy. Whereas earlier technologies prevailed for hundreds of thousands or even millions of years and only changed with the arrival of a new species, after 50,000 BP material culture evolves rapidly and differentiates without any corresponding physical changes. Human cognitive capacity had apparently reached a state of dynamism and flexibility whereby it could innovate cultural adaptations ad infinitum.

In addition to the hafted stone and wood tools characteristic of Mousterian culture, *Homo sapiens* now began to fashion a host of new and more delicate tools from bone and antler, creating hooks, needles, awls, and harpoons. They wove fibers into ropes and clothing, tanned hides for clothing and coverings, created jewelry and other forms of personal adornment, and built permanent shelters that included not only hearths but also lamps and kilns. They invented spear throwers, bows, and arrows to allow effective hunting from a distance, thus minimizing risks to personal safety. Late in the neolithic, bronze began to replace flint in tools and weapons, ushering in a “bronze age.”

Perhaps not immediately but sometime after the appearance of *Homo sapiens*, speech developed to give human beings a capacious verbal mem-

ory and new capacities for cognition and analysis.⁴⁷ The development of language was accompanied by important changes in the size, structure, and function of the brain. Expansion of an area located toward the bottom of the frontal lobes (Broca's area) permitted phonology, the making and controlling of sounds. The development of the temporal lobes (Wernicke's area) allowed audition, the ability to hear and differentiate sounds, and the expansion of the parietal and frontal lobes permitted conceptualization, the ability to use and manipulate arbitrary sound symbols in meaningful ways, that is, to think of words before uttering them and to organize them into large units of meaning. All of these expanded brain functions were connected into a larger articulatory loop that functioned in a newly coordinated fashion.⁴⁸

Language emerged not to give humans a capacity for rational or abstract analysis per se—this was more of a by-product—but instead to enhance their social intelligence so as to get along in large groups.⁴⁹ Language is the ultimate social arbiter, allowing people to maintain interpersonal relationships through conversation, to monitor the social interactions of others through gossip, and to reach collective decisions through discussion. In British anthropologist Robin Dunbar's words, "humans have bigger, more complexly organized groups than other species simply because we have a larger onboard computer (the neocortex) to allow us to do the calculations necessary to keep track of and manipulate the ever-changing world of social relationships in which we live."⁵⁰

As a means of maintaining social contact and monitoring interpersonal relationships, language is far more efficient than grooming for the simple reason that we can talk to more than one person at a time. The group size predicted for human beings from their cranial capacity is around 155 persons, which corresponds closely to the maximum size observed among hunter-gatherer societies.⁵¹ Comparing the group size of chimps to that of humans (55 to 155) suggests that whatever mechanism replaced grooming as a means of achieving group cohesion was three times more efficient. Unobtrusive studies of conversations conducted across a variety of cultural and social settings reveal that human conversation groups naturally gravitate toward a configuration of one speaker and three listeners. Moreover, whereas chimps spend about 20 percent of their time grooming, humans spend around 20 percent of their time in social interaction, mostly in conversation.⁵² Thus, language replaced grooming and built upon gesture as a means of ensuring social cohesion within large groups.

All human societies possess a spoken language, and all human beings are capable of learning any linguistic system. Indeed, as Noam Chomsky and Steven Pinker suggest, human beings possess a "language instinct."⁵³ Given appropriate exposure in childhood, any person anywhere can learn any language with a minimum of effort and without formal instruction. In contrast, even after intensive training throughout

Language emerged not to give humans a capacity for rational or abstract analysis per se—this was more of a by-product—but instead to enhance their social intelligence so as to get along in large groups.

childhood, chimpanzees cannot learn to speak any language, and even though they can learn to recognize 150–200 symbols, they cannot use them in grammatical fashion.⁵⁴

Despite its evolution as an instrument of “social intelligence,” however, language also offered humans new possibilities for rational analysis. Through vocabulary, syntax, and grammar, languages inevitably create categories of perception for time, objects, and events in the real world. Languages thus create a conceptual model of the universe and how it works, permitting the invention of what Richard L. Gregory calls “mind tools,”⁵⁵ categories of thought that facilitate other mental operations. The emergence of language is thus associated with the emergence of a new kind of “mythic culture” in which humans developed symbolic metaphors to explain the operation of the universe.

The appearance of musical instruments, rhythmic devices, lunar calendars, and various other symbols in the millennia from 50,000 BP to 10,000 BP testifies to the growing importance of myth in society. Burial of the dead indicates the importance of ritual, and interment with utensils, food products, and jewelry indicates a belief in the afterlife.⁵⁶ The first symbolic art appears in the form of sculptures and cave paintings and, given the remote location of most cave art deep in the interior of inaccessible caverns, obviously served some symbolic ceremonial purpose.⁵⁷ Mythic culture, for the first time in history, allowed humans to synthesize discrete time-bound events and circumstances and to connect them into a single coherent narrative to explain the world. Mythic culture did not supplant episodic and mimetic culture; it was superimposed upon them and extended a preexisting emotional infrastructure. Every hunter-gatherer society thus has an elaborate mythic system that permeates daily life and, through the use of verbal and nonverbal symbols, gives meaning to everyday objects, circumstances, and events.⁵⁸ Myth constitutes a “symbolic web” that explains how people are supposed to behave, why cultural rules must be obeyed, and how they are to be enforced.⁵⁹ God myths in particular reflect a society’s idea of causality: where life comes from, what happens to people after death, and what controls events in the world.

When considered comparatively across time and space, hunter-gather societies are found to share a variety of traits.⁶⁰ They occupy large territories at low densities and are characterized by geographic flexibility and a lack of attachment to fixed settlements. They are unstratified, with few social distinctions except for those based on age and sex. Males and females are distinguished from one another in both ritual and subsistence, and adults take care of children and the elderly.

Most groups possess social mechanisms to distribute food and prevent the accumulation of surplus. They employ a universal classification of people according to kinship and have a symbolic structure based on bipolar opposites (good-bad, male-female, hot-cold, etc.). Their metaphoric narratives associate animal identities with those of humans, and much of human action is infused with ritual.⁶¹ Although possessing a capacity for rational thought, elements of rational cognition and culture are not very well developed in mythic cultures. Rather, the new cognitive apparatus created by words was more strongly connected to emo-

tional centers of the brain through conditioning and learning that was deliberately reinforced by ritual, ceremony, and spirituality.⁶²

Urbanism as a Way of Life

The signature characteristic of foraging societies is that except for the very young and the very old, everyone produces food: each day all able-bodied people move about the environment hunting and gathering to ensure a caloric intake sufficient to survive another day. Until quite recently, human societies had no specialists devoted to tasks other than food production and certainly none devoted to full-time cognition. The leisure time necessary to think broadly and deeply only became available between 12,000 and 10,000 years ago with the emergence of the first sedentary villages, a new social configuration rendered feasible by the invention of agriculture and the domestication of animals. For the first time in human experience farming created a food surplus, and the accumulation of calories above one day's needs enabled a dramatic acceleration of human population growth, higher population densities, and the emergence of a new class of people—urbanites—who did not have to produce food for their own survival.⁶³

The leisure time necessary to think broadly and deeply only became available between 12,000 and 10,000 years ago with the emergence of the first sedentary villages, a new social configuration rendered feasible by the invention of agriculture and the domestication of animals.

Agrarian Urbanism

Agriculture, herding, and cities emerged at different times in different places depending on access to plants and animals that were potentially domesticable,⁶⁴ but they first materialized in a geographic arc extending from the eastern Mediterranean upward through Anatolia and down into the valley of the Tigris and Euphrates rivers. Known as the Fertile Crescent, it was here that the ancient ancestors of several modern cereal crops and herd animals were found in foothills adjacent to a flat alluvial plain whose soil was annually replenished and watered by seasonal flooding, yielding the perfect environment for the emergence of intensive agriculture. Wheat, barley, and peas were domesticated in Mesopotamia by 10,000 BP, along with sheep and goats; by 6000 BP several fruit-bearing trees and bushes had also been tamed (notably those yielding olives and grapes). Agriculture was independently invented in China, Mesoamerica, and perhaps India, but mostly agrarianism spread to other regions through diffusion.⁶⁵

The domestication of plants and animals set the stage for a new kind of human society based in cities. The first cities emerged in Mesopotamia around 8,000 years ago, with populations in the 5,000–25,000 range.⁶⁶ Under a preindustrial technology, the amount of food that could be produced per acre was limited, and the total size of the food surplus was

necessarily meager. While intensive agriculture may have permitted cities to exist, they could not be numerous, and most people could not live in them. Prior to the industrial revolution, no more than 5 to 9 percent of most societies lived in cities, and the total population of a single city never exceeded 1 million.⁶⁷

With yields per hectare fixed by technological limits, the only means for a city to become larger was to gain control of more land and thereby to commandeer a larger surplus. Mesopotamian cities were limited in size by internecine rivalries and political fragmentation. It was not until the pharaohs consolidated their control over the Nile River valley around 5,000 years ago that cities really began to expand. The first settlement to exceed 100,000 inhabitants was Thebes, in Egypt, around 3,400 years ago. It was succeeded 1,000 years later by Babylon, which surpassed 200,000, and finally by Rome, which during the reign of Caesar Augustus was the first city to surpass 500,000.⁶⁸

Wherever it occurred, agrarianism displaced hunting and gathering as a way of life through direct conquest, demographic absorption, or ecological marginalization. This victory occurred not because agrarianism provided people with less work, better nutrition, and longer lives. On the contrary, the residents of early agrarian societies worked longer hours, consumed fewer calories, lived in poorer health, and within cities died in larger numbers.⁶⁹ What gave agrarian societies their decided advantage in confrontations with hunter-gatherers was their demographic weight, which allowed them to possess an advanced technology, specialized fighters, and much deadlier germs.

With the advent of agriculture, the stone age gave way to the bronze and iron ages, and metals replaced flint to create more effective tools and more lethal weapons. Urban dwellers and the empires they ran evinced new instrumental needs, specialists thought up new tools to satisfy them, traders obtained the necessary raw materials, artisans made them, a political elite controlled their distribution, and a religious elite justified their deployment. As a result, in any encounter agrarian societies were able to wield weapons and technologies far superior to anything that hunter-gatherers could muster.

Agrarian societies also had more people spared from the necessity of food production to wield these weapons, leading to the emergence of professional soldiers and the first standing armies. In any competition over land and resources, populations enumerated in the tens or hundreds of thousands held a clear advantage over small bands numbering in the dozens or hundreds, especially if the former fielded an army of well-equipped, well-fed, and well-trained professional fighters.

Finally, the density of preindustrial cities, the lack of sewage facilities, the contamination of drinking water, and the close association of humans with animals gave one final advantage to agrarian societies: germs.⁷⁰ Until the nineteenth century, in fact, health conditions in cities were such that infectious diseases were endemic and life expectancies were short, much lower than among peasants in the countryside.⁷¹ Were it not for continuous rural in-migration, preindustrial cities would not have been able to sustain themselves demographically.

Table 2. Eras in the evolution of human nonforaging societies

	Agrarian	Industrial	Postindustrial
Beginning date	10,000 BP	200 BP	20 BP
Duration	10,000 yrs	180 yrs	20+
Generations	500	9	1+
Inhabitants	H. sapiens	H. sapiens	H. sapiens
Cranial capacity	1,450 cc	1,450 cc	1,450 cc
Sustenance	Agriculture	Manufacturing	Knowledge
Tools	Bronze & iron	Steel alloys	Silicon, plastic
Kind of culture	Mythic	Theoretic	Theoretic
Settlement type	City	Metropolis	Megalopolis
Community size	1 million	20 million	30 million
Human population	970 million	6 billion	9 billion

Although death rates were high and life expectancies short, those urban dwellers who survived either inherited or acquired an immunity to bacteria, viruses, and other parasites that hunter-gatherers could never attain, given their low densities. As a result, throughout history initial contacts between hunter-gatherers and urban-led societies have invariably led to the former's decimation through a sudden exposure to diseases for which they had no natural immunity.⁷²

From the rise of the first city-states around 10,000 years ago to the year 1800, agrarianism was the dominant form of human society, occupying ever-larger portions of the world's geography with ever-larger populations, both rural and urban. The rough trajectory of world population growth is indicated in Table 2, which graphs the estimated size of the human population from 600 BCE to 1800 CE. At the end of the Paleolithic era the world's population stood at around 8 million, but over the next 8,000 years it grew to reach about 252 million in the year zero. Under the Pax Romana population growth reached a plateau, and with the collapse of the Roman empire it declined to around 200 million before rebounding slowly after the year 600. Beginning in the year 1000, a variety of technological and social innovations came together to unleash a demographic boom in Europe, which proceeded apace until the Black Death struck in the mid-1300s (Levine 2001). As the foundations for a global economic order based on mass production, trade, and investment were established after 1600,⁷³ the human population entered an era of sustained exponential growth that accelerated up to the dawn of the nineteenth century, when the world's population stood at around 954 million.⁷⁴

In the 500 generations preceding 1800, the proportion of people living in urban areas rarely exceeded 5 percent,⁷⁵ and before that date only 65 cities in the entire history of the world had ever achieved populations over 100,000.⁷⁶ The vast majority of people in "civilized" agrarian societies of the past were illiterate peasants who lived in small villages

and isolated hamlets that were not much bigger than the hunting and gathering communities of the Paleolithic era. Work was governed by the rhythms of the seasons, and most people lived and died within a few miles of where they were born, spending all their lives within a community of friends and relatives they knew personally. In such a society, culture remained substantially mythic. The only real difference compared with the mythic cultures of hunter-gatherers was the patina of formal structure imposed from above by a priestly class.

By innovating written languages, however, agrarianism created the foundations for a new kind of culture. The earliest known origins of writing lay in the desire of Sumerian merchants for an accounting system to keep track of sales and shipments. Some 10,000 years ago, urban traders began using a stylus to mark clay tokens of different shapes, thus indicating the quantity and nature of goods being shipped or stored.⁷⁷ Over the millennia, these clay tokens expanded into tablets and the markings were elaborated until round 5,000 years ago they became a syllabic script for the Sumerian language. About 4,000 years ago, the Phoenicians evolved the first phonetic alphabet, which was later borrowed and modified by the Greeks and eventually the Romans, whose system we use today.⁷⁸ Writing developed in China at about the same time, at least by the eighteenth century BCE, and was standardized across China during the Qin dynasty (221–206 BCE). From there, Chinese writing scripts spread across Asia.

The advent of writing created the first external memory devices—tablets, scrolls, and stone monuments—that dramatically reduced the demand on biological memory and freed up human cognition for other tasks. Whereas biological memory is inherently limited by a fixed number of neurons, writing created a storage system of unlimited size. Moreover, by allowing connections between individual brains within dense urban environments, writing dramatically increased the size of the human cognitive apparatus.⁷⁹ In many ways, cities functioned as macro-social “brains,” and the use of external symbols externalized thought and dramatically increased information processing.⁸⁰

In many ways, cities functioned as macro-social “brains,” and the use of external symbols externalized thought and dramatically increased information processing.

Writing thus created the potential for a new theoretic culture, a logical system of thought grounded in experience and rationality and capable of making accurate predictions about events in the natural and social worlds.⁸¹ Almost by definition, access to such a culture was limited to the small minority of people who were literate and were freed from the burdens of food production, and even among those who could read and write there were two competing modes of thought.⁸² Narrative thought is basically a written extension of oral culture expressed as literature: plays, poems, stories, novels, operas, etc. Analytic thought, while dependent on words, is a rational construction grounded in formal systems of argument, taxonomy, and conceptualization, which follow logical rules based on induction and deduction and make frequent use of formal quantitative measurement. Although theoretic culture gained

adherents and influence in human affairs during the agrarian era, it necessarily remained a minor part of the total human experience, given the small number of people who were literate.

Industrial Urbanism

All in all, agrarian urbanism proved to be a relatively stable and durable social system. Although numerous empires came and went in the 9,000 years from approximately 8000 BCE to 1000 CE, the basic contours of urban society remained largely unchanged. Throughout the period, city size was limited by the area of the agrarian hinterland; the rate of urbanization was limited by low productivity in agriculture; communication required physical travel by human beings; the fastest transport was by sail over water, and overland travel was slow, costly, and dependant on animal power; goods were manufactured by skilled artisans fabricating one item at a time within a single workshop; stratification was rigid and social mobility limited; few markets existed; and social interactions continued to be dominated by relations of communal sharing and equality matching, overlaid with a veneer of authority ranking imposed by urban elites.⁸³

Empires persisted for hundreds and even thousands of years without changing their basic structure, organization, or culture. Somewhere around 1,000 years ago, however, the world began to change in important ways. Innovations in political organization and technology gave birth to a material revolution that vastly increased human productivity and released cities from technical limits on their size, density, and number. The collapse of the Roman empire in 476 CE brought about a marked decline in urbanism throughout western Europe as cities, markets, and trade routes withered and gradually fell away.⁸⁴ Although large swaths of the former Roman empire were absorbed into the successor agrarian states of Byzantium, the Islamic caliphates, and for a time the Carolingian empire, after 1000 most of western Europe languished outside of any centralized polity and was divided into a series of small independent kingdoms that competed with one another in a shifting patchwork of alliances known as feudalism. Although feudalism, like agrarian urbanism, rested on an agricultural base, its politics were quite different compared with those of the agrarian empires that had gone before.

Whereas agrarian states imposed political order from above using military force and administrative power, a new technology of warfare changed the calculus of political domination in feudal Europe.⁸⁵ With the adoption of the stirrup, mounted horsemen in heavy armor acquired a decisive battlefield advantage over infantry, bowmen, and regular cavalry. Maintaining a knight in the field, however, required a rather large capital investment that was beyond the capacity of a single lord. Feudalism emerged as a means of financing this new man of war. Vassals were granted suzerainty over a territory and its people, from which they were expected to support themselves as knights. The knights—basically the armored tanks of their day—were then expected

to remain on call as soldiers to defend the king's interests.

Under feudalism, an all-powerful sovereign did not issue imperial orders from above but instead contracted with semiautonomous lords who offered arms in return for socially defined privileges. These lords, in turn, negotiated a social compact with peasants who then surrendered their labor and agricultural produce to support their squire's knightly enterprise in exchange for other rights and privileges. Although feudal relationships may have been decidedly asymmetrical and unequal, they were nonetheless negotiated and therefore fundamentally different from the politics of empire that had transpired before.

The dynamic Han empire of China fell in the third century of the modern age, and China went through a period of disunity from about 220 to 581 BCE, but trade across the Silk Roads and around the Indian Ocean basin never really ended and enjoyed a resurgence around 1000. Cities also came to acquire semiautonomous power in the feudal order.⁸⁶ Urban merchants began to rebuild the trade routes and markets that had shriveled with the demise of Rome, and they extended new trade routes into northern and eastern Europe and the Islamic empires of northern Africa, the Middle East, and Spain. The revival of trade brought

about a resurgence of markets, the reintroduction of currencies, and a new burst of capital accumulation.

As a result, urban merchants offered kings and nobles an attractive source of tax revenue to support their knightly ambitions.

In return for granting merchants the freedom to pursue commercial interests, make investments, and reap profits, the royals and the landed gentry imposed tolerable rates of taxation. Urban merchants and feudal lords shared a common interest in local autonomy and commercial freedom. Because of the granting of limited rights of self-government to cities, more wealth was produced by merchants to provide more tax revenues for the knightly enterprise.⁸⁷

The Roman Catholic Church, meanwhile, provided a multilateral framework that held the whole system together. The expansion of papal power, in particular, provided a semblance of international stability and global governance.⁸⁸ At about the same time, Gregorian reformers inserted themselves into medieval social life, forcing celibacy on a reluctant priesthood, restricting sex to marriage, and making primogeniture the basic rule of inheritance. This ecclesiastical revolution created a new family

system characterized by late marriage, widespread spinsterhood, and inheritance of property by the eldest male, providing both monasteries and commerce with a ready source of recruits from among the younger sons of landed families.⁸⁹

The new family system slowed population growth by reducing the number of married women and thus the number exposed to the risk of childbearing. Primogeniture, meanwhile, limited the fragmentation of landholding. These social changes occurred in tandem with technological innovations that raised agricultural productivity, namely the introduction of the iron plow, new methods of crop rotation, the substitution of horses for oxen, and the application of wind and water power for the milling of grain.⁹⁰ As a result of these and other changes, the food supply increased, peasant households reproduced, and European population densities rose in both towns and the countryside.

By around 1340 even the most marginal lands were in production, and feudalism was on the verge of sinking into a low-level equilibrium trap whereby population growth overwhelmed land resources to create chronic food shortages.⁹¹ The event that prevented this cycle of economic decline from setting in was the arrival in 1348 of the Black Death, a flea-borne plague that killed rich and poor alike, city dweller as well as rural villager, and within a few years cut populations across the Eurasian landmass by about one-third.⁹² This massive wave of mortality transformed the social order in several important ways.⁹³

First, by opening vacancies at the top of the social hierarchy, the high mortality rate created new possibilities for social mobility from below. Second, by reducing the number of workers, it enhanced the bargaining power of labor and enabled workers to renegotiate the terms of their social contracts, leading to a rise in wages and the creation of nascent labor markets. Third, rural population loss led to farm abandonment and the emergence of the first land markets. Fourth, because the plague killed people but left capital untouched, it dramatically increased capital-to-labor ratios, yielding a sudden, if perverse, surge in capital formation. Finally, the experience of massive mortality reoriented the outlook of those who survived, prompting them to focus more on the fruits of this world rather than on promised rewards in the next.

Once the plague had run its course, the stage was set for the emergence of the modern world. All that was needed was a set of new technologies that could increase productivity enough to support a large nonagrarian population. The invention of the blast furnace in 1621 made possible the mass production of steel and offered a cheap metal that was strong enough to contain boiling water under pressure, leading in 1698 to the invention of the steam engine. Although the original engine was inefficient and of little practical use, its design was improved in successive steps until 1765 when James Watt of Scotland added a separate condenser connected to a cylinder by means of a valve, thus allowing the condenser to remain cool while the cylinder was hot.⁹⁴

Watt's patented design yielded a steam engine that efficiently converted heat from burning coal into mechanical power that could be applied to a wide variety of practical tasks. The productive potential of the steam engine was fully realized when it was combined with a social

reorganization of manufacturing that broke production down into a series of discrete but interconnected steps. Rather than occurring in small workshops where one artisan or a few artisans worked on one item from start to finish, production was reconfigured to occur in a cooperative division of labor that involved a large number of people applying machine power independently in coordinated fashion across a series of discrete steps that were linked together to form an integrated productive process.

This revolution in social organization combined with steam technology enabled human beings to fabricate a very large number of standardized items at very low marginal cost. The end result was a revolutionary increase in human productivity: the ability to produce a vast array of goods with relatively modest inputs of human labor. The Industrial Revolution emerged in England as steam power was applied to transform the cotton and woolen industries. After the invention of spinning frames and mechanized looms in the late 1760s, textile mills were established along rivers. But after 1780 Watt's steam engine was substituted for water power, and mechanized plants began to spring up throughout the English Midlands. Between 1780 and 1840 the production of British textiles increased by a factor of 50, creating vast new fortunes among the entrepreneurial factory owners.

In the 1770s factory methods were first applied to agriculture, and the introduction of the steel plow in 1837 dramatically increased farm production to overcome the historical imbalance between population growth and food supply, which up to then had held population growth in check.⁹⁵ After 1820 British entrepreneurs and engineers applied steam power successively to a growing array of manufacturing processes to create a plethora of new products that were sold to paid laborers who, in turn, spent their resulting earnings to buy the manufactured products on expanding urban consumer markets.

In 1787 steam power was harnessed to a propeller and used to drive ships through water, and by 1807 the first commercial steamship line had been established, thus providing a quick, reliable, and inexpensive means of transoceanic and riverine travel. Steam power and factory organization soon spread across the English Channel to Germany and the Netherlands and then moved steadily south and east to reach Russia by 1851, Italy by 1854, and Spain by 1859.⁹⁶ By 1870 steam power had jumped across the Atlantic to launch industrialization in the Americas, notably in Argentina, Canada, Brazil, and the United States.⁹⁷

In 1800 the first steel suspension bridge was built, and in 1804 the first steam locomotive was constructed, finally liberating human beings from their dependence on animate power for overland movement. With the advent of railroads, cost-effective transportation for the first time could be supplied to human settlements regardless of location or terrain.⁹⁸ The telegraph was invented in 1837, and railroad beds were put into service as clear corridors for cables to create an integrated network of transportation and communication linking the new industrial cities to one another. The first transatlantic telegraph cable became operational in 1857. With the advent of the telegraph, for the first time in human experience a person did not have to travel physically through

space to transmit information from one place to another. The functions of transportation and communication began to separate.

All of these technological changes brought about the massive societal transformation we know as the Industrial Revolution. At the dawn of modernity, in the year 1000, gross world product (GWP)—the total value of goods and services produced by human beings throughout the globe—is estimated to have been around 102 trillion dollars.⁹⁹ Seven hundred years later it reached 370 trillion dollars, for an average growth rate of just 0.2 percent per year between 1000 and 1700. As small as this rate of growth was, it was still much larger than that prevailing over the prior nine millennia. After 1700, however, the pace of economic production accelerated dramatically and surged after 1800 to reach exponential levels. Between 1800 and 1900, the GWP increased from 640 trillion dollars to 5,336 trillion dollars, for an average annual growth rate of 2.1 percent, a tenfold increase over the period 1000–1700 and a quantum leap over the rates of economic growth that had prevailed under agrarianism.¹⁰⁰

The Industrial Revolution likewise enabled a sustained increase in population after 1600, and the number of human beings on earth accelerated and population growth also reached exponential levels after 1700. Most of the new people were absorbed by urban areas, and in 1800 the share of human beings residing in cities accelerated greatly, escaping the cap that had constrained human societies since the invention of agriculture. After nearly 10,000 years of low-level stasis, the level of global urbanization grew rapidly to 28 percent in just 150 years, from 1800 to 1950.¹⁰¹

Impressive as this gain in urbanization may seem, it fails to convey the full scale of the transformation that was occurring in the world's industrializing societies. Urbanization in less developed regions only began to rise around 1900 and in 1950 still stood at just 17 percent. In contrast, urbanization in developed regions began a century earlier and by 1950 had reached 53 percent. For the first time in recorded history, an absolute majority of a society's members was able to live in cities rather than the countryside. Remarkably, in Western Europe and North America almost two-thirds (64 percent) had become city dwellers by the mid-twentieth century.¹⁰²

Although the interconnected revolutions in food production, manufacturing, transportation, and communication enabled the number, population, and geographic range of cities to increase, until late in the nineteenth century urban densities were still constrained by two technical limits. The first was medicinal: as long as infectious diseases remained outside of human control, urban mortality continued at high rates to create a permanent structural imbalance between births and deaths that offset the positive effect of in-migration to inhibit urbanization. Although the first successful vaccination occurred in 1796, it was not until 1881 that Louis Pasteur proved the germ theory of contagion

With the advent of the telegraph, for the first time in human experience a person did not have to travel physically through space to transmit information from one place to another. The functions of transportation and communication began to separate.

to provide public officials with the scientific knowledge they needed to bring urban mortality under control. Municipal investments in water purification, sewage treatment, and housing in the late nineteenth and early twentieth centuries caused urban death rates to plummet and reversed the historical rural-urban mortality differential.¹⁰³ It soon became safer to live in cities served by efficient water and sewage systems and near hospitals and clinics than in the countryside.

The second limitation on density was mechanical: the inability to build very far upward. In theory, the availability of milled steel might have permitted humans to construct metal-framed structures as early as the eighteenth century, but heights were still constrained by the reluctance of people to walk up more than four flights of stairs on a regular basis. Density was also limited by the inability to heat, light, and ventilate large multistory buildings without suffocating, freezing, or cooking the inhabitants. These technical constraints were overcome with the adoption of electricity as a means of transmitting and distributing power.

The first electric generator was built in 1831 by Michael Faraday, and after 1870 the first coal-fired generators were placed into service, followed in the 1880s by the first hydroelectric dams. Elisha Otis invented the elevator in 1852, and once electric power became widely available, he began installing elevators in tall buildings throughout the developed world. Suddenly people could travel up and down dozens of floors effortlessly, and the four-story height ceiling was permanently breached: the era of the skyscraper had arrived. At the same time, the invention of the incandescent light bulb (1879) and the electric fan (1882) provided solutions to the long-standing problems of heating, lighting, and ventilating interior spaces, and the invention of the telephone in 1876 allowed instantaneous communication between floors, not to mention across town. With the last of the technical constraints lifted, urban population densities exploded in the nineteenth and early twentieth centuries to make urbanism possible as a way of life for a majority of those living in developed societies.

Postindustrial Urbanism

Dating the end of one era and the beginning of another is always an exercise in the arbitrary. Nonetheless, it is clear that sometime during the 1970s the reign of industrial urbanism came to an end. For a variety of reasons, the critical moment seems to have been around 1975. The mid-1970s coincided with a severe recession throughout the industrial world, the appearance of a new malady known as stagflation (high inflation combined with high unemployment), the end of a 30-year rise in median income, the bottoming out of the equally long decline in poverty rates, and a sharp turnaround from falling to rising income inequality.¹⁰⁴

Whatever the precise date of the transformation, the industrial era proved to be of remarkably short duration. Compared with the 40,000 years of foraging and the 10,000 years of agrarianism, the 175 years of industrialism was short indeed. If human beings did not have sufficient time in 500 generations to evolve genetic adaptations to agrarian urban-

ism, they certainly could not do so in the eight generations that encompassed the rise, peak, and decline of the industrial order. Just as human beings in preindustrial and industrial cities were more adapted physiologically, psychologically, and socially to foraging as a way of life, so too are the inhabitants of today's postindustrial urban landscapes.

Through the nineteenth and early twentieth centuries, wealth accumulated within industrial cities at an unprecedented rate. At the same time, educational levels steadily rose, mortality rates fell, and the pace of technological innovation quickened. Although socioeconomic inequality increased as well, new social movements emerged to press for reform, and by the second decade of the twentieth century they had begun to achieve significant redistributions of power and wealth in a growing number of countries.

For intellectuals, politicians, and the public, the continued march of progress under the banner of industrialism seemed inevitable. Faith in the inexorability of human improvement died violently, however, with the outbreak of World War I in 1914. Known in its day as the Great War, its causes were complex and are still much debated.¹⁰⁵ Perhaps the simplest explanation is that global trade proceeded too fast and moved too far ahead of global governance.¹⁰⁶ In 1914 the world lacked a set of multilateral political institutions capable of adjudicating disputes and diffusing the tensions that inevitably arose from a more intense interaction of nations within a globalizing economy.

Whatever the precise causes of the war, the end result was four years of horrific bloodletting among the world's industrial powers. The profligate, wholesale destruction of land, labor, and capital during the Great War sowed the seeds for economic collapse in the era that followed. When the war finally ended in 1918, international political stability was gone. The regimes of most belligerent nations had been overthrown, and the nascent system of international economic institutions crafted in the late nineteenth century lay in tatters.¹⁰⁷ World War I opened a Pandora's box of contradictory forces, and it would take most of the twentieth century to reconcile them: the intensification of the struggle between labor and capital, the polarization of political ideology between communism and fascism, a widespread retreat from liberal democracy among former trading nations, and the fatal wounding of one hegemonic power and the reluctance of its successor to assume the mantle of responsibility.

Reflecting these paralyzing contradictions, the period 1918–1945 witnessed the collapse of international trade, the rise of autarkic economic nationalism, and the widespread implementation of chauvinistic restrictions on trade, investment, and immigration.¹⁰⁸ Although the world economy hobbled along for a while on the strength of wealth accumulated in Oceania and the Americas during the Great War, the global system of trade and investment finally came crashing down in 1929. Laws

For intellectuals, politicians, and the public, the continued march of progress under the banner of industrialism seemed inevitable. Faith in the inexorability of human improvement died violently, however, with the outbreak of World War I in 1914.

passed by an isolationist U.S. Congress during that decade progressively choked off international flows of people, goods, ideas, and capital, ultimately producing an economic meltdown of unprecedented depth and duration.

During the years of the Great Depression, international trade, capital formation, and industrial expansion all but ceased, and technological progress slowed to a crawl.¹⁰⁹ Following ten years of social, economic, and political turmoil, the ideological contradictions unleashed in 1914 were partially resolved on the battlefield between 1939 and 1945, as a coalition of communist and liberal democratic states arose to defeat fascism in the Second World War. Hostilities ended in 1945, with much of the industrial world bombed into ruins and the world polarized into conflicting ideological camps.

Because of this unique history, the social and spatial forms associated with pre-1914 industrial urbanism were largely frozen in time through 1945 and changed slowly for three decades thereafter especially in the United States, which never suffered physical damage during the years of violent warfare. Although telltale signs of the new postindustrial order were evident in North America as early as the 1920s, the economic collapse of 1929 and the virtual absence of private investment through 1945 meant that the basic social, economic, and spatial infrastructure of industrial cities persisted more or less unchanged through 1950, when urban industrialism may be said to have reached its zenith. On or about that year, the population, wealth, employment, and influence of U.S. central cities peaked.

Over the next 25 years economic growth continued under institutional arrangements developed largely during the 1930s in response to problems of the 1920s, a social compact among workers, owners, and professionals generally known as the welfare state.¹¹⁰ Although its specific institutional manifestations varied from country to country,¹¹¹ the welfare state generally attempted to maintain balanced economic growth by regulating markets, protecting citizens against market failures, providing universal retirement and health care systems, and extending popular access to education and housing. Beginning in the 1970s, however, the institutions of the welfare state came under increasing pressure as a result of two notable developments: a revival of global trade and a return to rapid technological innovation.¹¹² Together these two macrostructural transformations gave birth to the postindustrial order.

As already noted, the end of the Second World War did not bring about a full resumption of global trade because of the armed standoff between liberal capitalist democracies and communist dictatorships. Billions of people lived outside of markets within command economies in China and the Soviet Union and their satellite countries. Millions more lived under autarkic regimes that sought to promote economic development internally by applying tariffs, capital controls, exchange regulations, and import quotas to insulate themselves from the global economy. The attempt to promote national economic growth by insulating domestic markets from the global economic forces was known as Import Substitution Industrialization.¹¹³ The period 1945–1975 was generally one of

state dominance in the political economy of both developing and developed nations.

Among Western industrial powers, the United States finally assumed the mantle of responsibility that it by rights should have assumed after World War I and took the lead in rebuilding a transnational market economy while attempting to correct the mistakes of the past. The United States joined with other liberal democracies to create a new, more effective international system to ensure international security, liquidity, convertibility, investment, and trade through multilateral institutions such as the United Nations (UN), the North Atlantic Treaty Organization (NATO), the World Bank, the International Monetary Fund (IMF), the General Agreement on Tariffs and Trade (GATT), and ultimately the World Trade Organization (WTO). Through these and other institutions, the United States supported the economic reconstruction of Europe and Japan and worked to facilitate their integration into the reconstituted global trading system.

These policies led to a revival of trade, first among industrialized nations and then, as decolonization proceeded, between the developing and developed worlds. As the reconstruction of Europe and Japan drew to a close, agencies such as the UN, the IMF, and the World Bank shifted their agendas to promote economic growth in developing nations and worked to facilitate their entry into the global market.¹¹⁴ During the 1970s and 1980s, newly industrialized nations such as Korea, Taiwan, Singapore, and Malaysia developed economically by selling manufactured goods to overseas markets in developed countries, a strategy that became known as Export Industrialization.

During the 1990s, this strategy became reified as the Washington Consensus and was imposed by the mandarins at the World Bank and the IMF on countries throughout the world. Rather than insulating domestic economies from global economic forces, the new strategy sought to achieve fuller incorporation into the international trade regime by reducing tariffs, relaxing capital controls, eliminating import quotas, downsizing government, privatizing state industries, and cultivating export markets.¹¹⁵

After 1975, flows of capital, goods, raw materials, and information increased and were accompanied by a revival of immigration, first among industrialized nations and then between developing and developed regions. During the 1970s trade increased sharply, finally equaling the share of gross national product (GNP) reached during the decade 1911–1920 (12.5 percent). At the same time, in absolute terms immigration surpassed the level it had last achieved during the 1920s. Until the 1990s, however, the global economy could not flower fully because nearly a third of all human beings were isolated from it within rigid command economies. Only with the fall of the Berlin Wall in 1989 were conditions ripe for a full return to international trade and the emergence of a truly global economy. With the collapse of the Soviet Union and the decisive shift of Chinese communist leadership away from command and toward market mechanisms, the world finally returned to a stage of integrated economic development that it had last achieved in 1914.

Over the final two decades of the twentieth century, both international migration and trade expanded to new and unprecedented heights. During the 1990s, for example, immigration surged to 9.4 million persons, while trade rose to almost 18 percent of GNP.¹¹⁶ At the dawn of the new century, therefore, the United States stood at the center of a new global economy characterized by the massive international movement of people, goods, capital, commodities, services, and information, leading during the 1990s to a remarkable burst of economic growth and wealth creation.

Despite the foregoing historical contingencies, the roots of the post-industrial revolution were ultimately technological. Industrial urbanism ended because its characteristic technologies were replaced by a new set of technical innovations that sparked a wholesale reorganization of human society. Electric motors replaced steam engines in manufacturing, gasoline engines replaced steam propulsion in transportation, satellite and cellular transmission replaced wire networks in communications, and digital processing using silicon chips and fiber optics replaced analog computation using mechanical switches and copper wires in information processing. These technical shifts led to a revolution in transportation, communication, computation, and production.

The accelerating pace of technological change during the post-industrial era is indicated by the annual number of patents filed in the United States from 1960 to 2000. During the 1960s and 1970s the pace of technological innovation was relatively stable, with the number of applications fluctuating at around 100,000 per year. Suddenly in 1984, however, the rate of innovation shifted sharply upward, with the number of patent applications doubling by 1994 and tripling by 2000. In the last decade of the twentieth century, some 2.5 million patent applications were filed, compared with just 1 million during the 1970s.

Never before had human society witnessed technical change on such a scale. Decreases in the cost and increases in the rapidity of transportation, communications, and computation after 1970 turned the economic logic of the industrial order on its head. Whereas the material foundations of industrial society lay in the manufacture of standardized goods within large stable institutions, the economic basis for postindustrialism was the production of symbols—ideas, knowledge, and information—within small flexible institutional settings. The new postindustrial regime did not favor economies of ag-

glomeration and scale, mass consumption, homogenous markets, or large centralized cities managed by hierarchical bureaucracies but instead favored dispersed production, segmented markets, and fragmented settlements linked by formal and informal networks managed by smaller and more compressed bureaucracies.¹¹⁷

Whereas the material foundations of industrial society lay in the manufacture of standardized goods within large stable institutions, the economic basis for postindustrialism was the production of symbols—ideas, knowledge, and information—within small flexible institutional settings.

The Future of Human Society

Over the past 10,000 years human society has evolved in stages from tiny populations of mobile foragers circulating through natural environments, to small populations of settled horticulturalists exploiting narrow ecological niches, to moderately sized cities presiding over large agrarian hinterlands, to densely settled industrialized cities within an urbanizing world, and to the present configuration of populous geographically expansive metropolitan areas containing nearly all members of postindustrial society. In the course of this evolution, people did not change physiologically as organisms; what changed were the social structures they created and the technologies they deployed.

For most of human history, the impetus for social change came from fluctuations in the environment that occurred over time and space. As groups encountered different ecological conditions in different locations and in historical epochs, they innovated social structures and technologies to adapt. Since the emergence of the first human beings, the various stages of societal evolution have unfolded at an accelerating rate, and the impetus for change has shifted from the environment to the social structure.

The symbolic revolution that occurred around 50,000 years ago led to the flowering of mythic culture as an adaptive tool, which led to new innovations in technology and microsocial organization that, in turn, enabled the domestication of plants and animals. Around 10,000 years ago the first cities emerged, which made possible a new kind of theoretic culture that further accelerated rates of social and technological innovation that combined to produce, just 200 years ago, an industrial revolution that accelerated population growth and allowed societies to finally surpass the urbanization threshold of 5 percent. The subsequent industrialization and urbanization of society led to exponential accumulations of wealth, knowledge, and technology to give birth, a mere 25 years ago, to a new postindustrial metropolitan order based on the production and manipulation of information within large de-concentrated urban agglomerations scattered throughout the globe.

In the twenty-first century, a growing majority of human beings will live in large densely populated urban agglomerations. In this environment, most interpersonal associations will be impersonal and occur in the context of markets and anonymous public settings. The inhabitants of postindustrial urban societies will not lose their ability to form lasting bonds of intense emotion, of course. While continuing to cultivate such primary relationships to achieve emotional satisfaction, they will increasingly engage in fleeting, superficial relationships to attain material and symbolic rewards. In quantitative terms, these secondary role relationship will increasingly dominate society.

Increasingly, human social interactions will be shaped by exposure to an urban environment of great size, density, and social heterogeneity. Within this brave new urban world, the character of the ecological setting in which people find themselves—and the nature of their psychological, social, cultural, and physiological adaptations to it—will vary

dramatically depending on whether they are rich or poor and whether they live in areas of concentrated affluence or poverty. Evidence suggests that a remarkable and widespread geographic concentration of deprivation and advantage occurred within postindustrial cities during the final decades of the twentieth century.

This concentration was brought about by the combination of rising socioeconomic inequality with growing class segregation, an interaction whose effects were exacerbated by segregation on the basis of race or ethnicity. Postindustrial societies are increasingly differentiated socially along three fundamental axes variation—socioeconomic status, ethnic status, and family status—and the geographic intersection of these axes within the urban landscape has produced a new correspondence among these dimensions.

A growing body of urban research suggests that people who grow up under conditions of concentrated poverty and deprivation display higher rates of joblessness, educational failure, single parenthood, income deprivation, family disruption, poor health, and cognitive impairment as adults, compared with those who grew up in areas of concentrated affluence. Inequality, class segregation, and the resulting concentration of affluence and poverty have thus produced a reification of the fundamental mechanisms of stratification leading to a tighter intergenerational transmission of socioeconomic advantage and disadvantage.

Ultimately, avoiding the creation of a hardened stratification system of durable inequality requires preventing further concentrations of affluence and poverty and rolling back those that emerged during the period 1975–1995. Such a change ultimately requires the effective implementation of policies to reduce inequalities with respect to income and wealth, lower levels of class segregation, and reduction of segregation on the basis of ascriptive traits such as race, ethnicity, and gender, which are the proximate determinants of ecologically concentrated wealth and poverty.

If the status quo continues, inequality will increase and racial-ethnic divisions will grow, yielding a volatile and unstable society for the twenty-first century. Urban areas in developed countries and the Third World can expect to experience escalating crime and violence punctuated by sporadic riots and increased terrorism as class and communal tensions rise. The poor will become disenfranchised and alienated from mainstream political and economic institutions, while the middle classes will grow increasingly angry, frustrated, and politically conservative. The affluent will continue to withdraw socially and spatially from the rest of society and seek to placate middle-class anger with quick fixes and demagogic excesses that do not change the underlying structure responsible for their problems. This scenario is by no means inevitable, and one can only hope that it will not come to pass. Yet this is the path down which we are headed unless self-conscious actions are undertaken to change course.

In this entry, cultural geographers Donald Rallis and Melina Patterson examine regions as the result of the interaction between geographic conditions—seas, mountain ranges, etc.—and human culture, perceptions, and heritage. The entry provides a very worthy lens through which to view the way in which humans form and maintain societies.

—Carolyn Neel

Regional Geography and World History

Donald N. Rallis and Melina A. Patterson

There are many ways in which we can consider the history of humans and their relationship with their surroundings. In this section, we present a short overview of world history from two perspectives. The first focuses on the significance of natural processes such as geographical and climatic conditions on human history. Next we consider the impact of human processes on the environment. However, before we can apply a regional framework to world history, we must first think critically about the concept of regions. There is a tendency to imagine that regions simply exist and always have, that those areas we see today as coherent units must have existed throughout time. However, regions are matters of convenience; they reflect our desire to generalize about places and peoples. A region is an idea that we use to organize information spatially. Today we define regions by their commonalities, by what they share, and thus we can identify linguistic, religious, precipitation, or soil regions (to give a far from complete set of examples). Regions, at any scale, can be imagined in an infinite number of ways for various intellectual projects. For example, climatic and cultural regions could both encompass the entirety of the globe but would have different boundaries. For our purpose, we treat regions as areas shaped by environment, culture, and ideas about the nature of places. In other words, our human understandings of self and other, here and there, home and not home, help create regions. All of these things—the environment, culture and ideas—change. The environment changes due to natural variability in rainfall and temperature patterns but also human actions. Cultures change over time due to internal causes as well as external contacts. The changes cause shifts in our collective understandings of how we live, or should live, in a particular place as well as our identity, our perception of who “we” are and who “they” are. So, regions are not static. The variables that define regions change over time, resulting in shifting regional boundaries. Looking at regions historically is a complex process. Any single regional division or framework reflects the perspective and realities of a particular historical moment; it will not fully or accurately represent the reality of other historical moments.

Commonalities define regions, so definitions of smaller regions will likely be more accurate because the area and the people in it will share more characteristics. For example, thinking about the Americas as a hemispheric region captures the degree to which the whole territory was a meeting ground between indigenous peoples and Europeans and to which certain aspects of those encounters, such as the importance of disease in destroying huge proportions of indigenous populations, were similar throughout the Americas. However, dividing the hemisphere into two, North and South America, recognizes the differences between Anglo-America (the United States and Canada) and Iberian America (from Mexico south) by recognizing the different religious and linguistic and political traditions that dominate each area. Dividing it further into North, Central, and South America further fine-tunes our view of the area, especially if we also divide Central America (from Mexico to Panama) into a mainland and a rimland. This last regional framework helps us discuss the complex social and economic world that emerged in the Atlantic islands and coastal areas of the Americas, where plantation economies dominated rather than the Hacienda-based organization of land and labor that characterized the mainland areas. And we could of course identify smaller regions still. However, dividing the world up into hundreds or thousands of regions limits the kinds of observations one can make about the world. Too much detail means not being able to see the big picture, after all. One other observation about regions follows from the example of the Americas. When we divide the hemisphere into North, Central, and South America and describe North America as “Anglo-America,” we ignore and deny certain realities, including the fact that much of the southwestern United States and California were part of Mexico until 1848. It was military conflict and politics, not just culture, that defined the borders of any North American region. The act of naming North America “Anglo-America” recognizes certain facts of history but negates others.

We should consider who defines regions and for what purposes. Today’s most common regional frameworks reflect the imprint of colonialism and the assumption that the nation-state is an almost natural unit. The idea of Africa and Southeast Asia as regions reflects the perceptions and influences of outsiders. The border between southern Asia and Southeast Asia, for example, reflects the historical realities of two different patterns of imperialism. Southern Asia includes all those contiguous territories of the British Empire in that part of the world. Southeast Asia is comprised of those territories that experienced a different form of colonial power. Contemporary regional frameworks generally try not to cut through nation-states because nationalism and state power are such powerful institutions today. However, they have not always been, so it is important to realize that in the past, regional boundaries would have had little relation to modern state boundaries. Regional divisions are expressions of current and recent power relations. When we discuss history through regions, we must remember that these regions came to be through the processes of history; they were not always delineated.

So, what regions will we use? We will use regions that exist or make sense in the early twenty-first century, regions that will make sense to most of our readers. But we acknowledge that this decision has some problems, and we will try to address them. Using contemporary regions might suggest that the regions that we see today were inevitable and that all of history has led to this particular natural, familiar arrangement of the world. However, not choosing contemporary regions would require using a set of regions so shifting that they would undermine using a regional framework at all or would result in a patchwork of regions defined by different criteria (e.g., the West, Incan civilization, China, the steppes). This framework suggests that some cultures were defined by particular historical moments and then were somehow frozen in time, while others progressed through time or were agents of history. This reinforces ideas about some places and peoples being backward and defined by tradition and others as representing modernity and progress. So, we have decided to use contemporary regional divisions and to focus on the major historical trends that have brought those regions into being. This means that with each region, we will discuss the particular environmental setting of one or more early cultural hearth areas (places of origin) and the social, economic, and cultural trends that extended various economic connections, cultural influences, and collective identities to broader social and environmental boundaries.

If today we understand regions as defined by commonalities—speaking English, practicing Buddhism, or the presence of high flat plains—it makes more sense to think of historical regions as defined by exchange and expansion. Economic exchange leads to cultural exchange in fairly direct ways, as the diffusion of Buddhism and, much later, Islam followed trade routes, for example. The expansion of empires would unite diverse groups of people into a single political unit, and while not every individual would come to understand themselves as part of that community, elites often would, and this would allow for new broader understandings of how people belonged to places. So our treatment of regions will focus on how historical processes led to the creation of our modern regional framework rather than assume that any regional framework would make sense at all historical moments.

All regions, however defined, have blurry edges, places that share some things in common with the rest of the region but have other things in common with those on the other side of a regional boundary. These blurry edges can be interesting places because they do not fit clearly into one region or another and because of what they reveal about the regions they border. Spain has often had a blurry boundary in Europe because of its location on the Mediterranean, today Turkey marks a complex border between Europe and the Middle East (and thus defining Turkey is one way that Europeans try to define what Europe means), and defining Egypt as part of Africa, as Mediterranean, as sharing Western (e.g., Greek) influences, as part of the Middle East, has been part of centuries of political projects. We will also focus on these blurry edges to explore the long-term production of regions, which is never complete and never neat.

Sub-Saharan Africa

Humans originated in sub-Saharan Africa, and since that time there have always been humans living in the region. Patterns of settlement, migration, and interaction have, however, changed over time. As elsewhere on earth, many of these changes have been strongly influenced by the physical environment. Indeed, the delineation of the region of sub-Saharan Africa is based on physical geography, bounded to the north by the Sahara desert and on all other sides by oceans. Its human geographies are also distinctive. Sub-Saharan Africa bears the strong economic, cultural, and political imprint of its colonial past, which may explain a bit about why it is presently the world's poorest region. All of this, however, gives a false sense of precision to the boundaries of the region. In part this is because the southern edge of the Sahara is not a fixed line. The desert expands and contracts with long-term climatic changes as well as seasonal and cyclical fluctuations in precipitation. Rather than envisaging a line separating northern and sub-Saharan Africa, it is more accurate to think of a transitional zone. This zone is the Sahel, an area of subtropical grassland between the savanna and the desert, an area subject to periodic droughts and, over the long term, to the ebb and flow of the Sahara. In recent decades the desert has been expanding southward, propelled in part by exhaustion of marginal agricultural land by the area's expanding population.

Just as there is no clear physical boundary to sub-Saharan Africa, so too is there no sharp boundary in the human landscape. Between the Arabs of northern Africa and the black Africans of sub-Saharan Africa is a zone of transition, a place that has been shaped over centuries by interactions between Africa's two main regions. For Africans, the northern Sahel has not been a barrier; it has been a zone of trade, commerce, and cultural exchange and also, all too frequently, a contested and conflicted place.

Physical Geography

Climate and topography have profoundly influenced the settlement patterns, trade, and colonization of Africa. Africa is a large continent about 20 percent larger than North America and about three times the size of Europe. Africa's coastline, however, is much shorter than Europe's, with fewer bays and natural harbors. The continent consists largely of high-lying plateaus: most of Africa lies at an altitude of over 1,000 feet above sea level, and half of the continent has an altitude of more than 2,500 feet. The coastal plain is narrow, and in some areas steep escarpments separate the interior from the coast. Rivers originating in the interior descend abruptly as they approach the coast, producing rapids and waterfalls. As a result, none of sub-Saharan Africa's rivers are navigable from their mouths into the interior of the continent.

Sub-Saharan Africa straddles the equator, and only the southernmost part of the region lies outside the tropics (see map of world climates). The equatorial regions of central and western Africa have tropical rain forest climates and are covered with forest vegetation that is rapidly be-

ing depleted by logging and the expansion of agriculture and human settlement. Farther away from the equator to both the north and the south are areas of tropical and subtropical savanna. These are the staple climatic landscapes of African wildlife documentaries, which are also important agricultural regions. These are in turn bordered by the semiarid steppe areas of the Sahel in the north and Kalahari in the south. Temperate climates dominate the extratropical southern African subcontinent. It is worth noting that the climates of the region are significantly affected by topography; the continent's interior would be significantly warmer if it were at a lower elevation.

Climatic patterns have influenced the history and human geography of sub-Saharan Africa in a number of important ways. A comparison between the map of African climates and the map of population distribution show a close (though by no means perfect) correlation. Deserts, semideserts, and some rain forest areas are the most sparsely populated; most of the region's people are concentrated in the more hospitable savanna and extratropical areas. Topography has also played a role in population distribution. In the west and southeast of the region, the densest populations are along the coasts; in the east, the interior Great Lakes region is where population is concentrated. What the population map does not show, however, are the ways in which sub-Saharan Africa's population distribution have changed over time, a change in its own way closely linked to physical geography.

Human Geography

Sub-Saharan Africa is predominantly populated by black Africans. All human and hominid life originated in sub-Saharan Africa. Today it is home to a diverse range of cultures and people. As Christopher Ehret discusses in *The Civilizations of Africa*, between 16,000 and 9000 BCE there were four separate African groups: the Afrasans, the Nilo-Saharans, the Niger-Congo people, and the Khoisans. These groups were innovative, leading to four distinctive cultural heritages, traces of which remain today. From the rise of early societies, there has been trade between northern sub-Saharan African societies, including the Sudanic civilization in the east and the Niger-Congo peoples in the west, and the Middle East. This contact was maintained even as climate change led to an expansion of the Sahara desert. Herodotus, a Greek historian and geographer, associated Egypt with high civilization—meaning that it was highly organized, stratified, and rich in arts and culture—and imagined that Ethiopia, a place he had never been, must be even more so. In the 1400s European maps of northern Africa were filled with images of wealth and economic activity. Only after the development of the slave trade did Europeans begin to imagine Africa as the Dark Continent. Perceptions of regions matter because perception shapes attitudes and actions. This particular perception had long-lasting implications.

It is impossible to understand sub-Saharan Africa in the twenty-first century without understanding the impact of colonialism on the region. Although it came late and in most cases lasted less than a century, colonization restructured sub-Saharan Africa economically, culturally,

CLIMATE REGIONS OF THE EASTERN HEMISPHERE

CLIMATE REGIONS OF THE WESTERN HEMISPHERE

politically, and socially. Colonization also imposed new geographies on the region: boundaries, populations, and political organization were reshaped by the colonial powers as a result of their presence. Clearing lands for farming, mining, or construction of roads and railways reshaped the land. These new geographies were invariably motivated by the interests of colonial powers rather than those of indigenous Africans. This meant that when decolonization came, Africa's newly independent states found that they were heirs to geographies designed by outsiders for outsiders, often ill-suited to African needs. It is a paradox of colonial history that sub-Saharan Africa, one of the closest world regions to Europe, should have been among the last to be colonized by Europeans. By the early sixteenth century, Europeans had begun their conquest of the Americas and had opened trade routes to Southeast Asia. By the mid-seventeenth century they had substantial colonies in both of the regions and in southern Asia. By 1850, several centuries of colonial rule had ended in most of the Western Hemisphere, distant Australia and New Zealand had been colonized, and the coastal areas of eastern Asia were under European domination. But in that same year, a map of colonial rule south of the Sahara desert would have shown that with the exception of South Africa, most of sub-Saharan Africa had not been colonized.

There had certainly been trade between Europe and sub-Saharan Africa, most notably in the form of the slave trade. This had a significant economic, cultural, and demographic impact on the areas from which the slaves came as well as the colonies in the Americas to which they were taken. But although the impact of the slave trade reached well into the interior of sub-Saharan Africa, this occurred without European colonization. Only in the 1880s, with the Scramble for Africa, did Europeans extend their political control into the continent. By 1905, all of sub-Saharan Africa, with the exception of Liberia and Ethiopia, had been claimed by European powers. The reasons that colonization came so late to sub-Saharan Africa are largely rooted in the region's topography and climate. For Europeans traveling along the western side of the continent, the deserts and rain forests (which together accounted for most of the coastline) appeared to offer few rewards and numerous hazards. Even if Europeans had sought to venture inland, the practical obstacles would have been daunting. In the coastal areas of western Africa, heat, humidity, dense vegetation, and disease presented significant problems. South of the Gulf of Guinea, narrow coastal plains, steep escarpments, and a lack of navigable rivers made it difficult to penetrate the interior overland or transport goods back to the coast.

Some of the same geographic considerations that kept Europeans from the interior of sub-Saharan Africa influenced the nature of sub-Saharan societies in the precolonial era. Nowhere is this clearer than in western Africa, a region with a history of civilizations and empires that predated the arrival of Europeans by many centuries (see map of Human Geography of Africa). The economic base of these societies roughly corresponded with latitudinal climatic zones. The economies of the tropical forest zone along the coast produced crops such as yams and palm

HUMAN GEOGRAPHY OF AFRICA

oil, whereas the inhabitants of the grassland Sahel region were pastoralists, a complementarity that gave rise to interzonal trade. Links also existed between western and northern Africa, along the Sahel region, and also across the Sahara. These were the routes along which Islam came to western Africa. Some of western Africa's largest and most powerful empires existed here, including Ghana, Songhay, and Mali. The administrative and trading centers of these empires were western Africa's main urban centers, among them Timbuktu, Gao, and Wadan.

When colonialism eventually engulfed sub-Saharan Africa, it did so rapidly and with profound consequences. Human geographies of the region were vitally changed by the colonists to serve their own needs, fundamentally altering indigenous societies and economies. Among the most vivid examples of this is the geography of political boundaries. As Europeans divided the African continent among themselves, they imposed colonial boundaries that bore no resemblance to preexisting indigenous cultural, political, or economic geographies (see map of African Country and Tribal Boundaries). In some areas, imprecisely demarcated or weakly enforced colonial boundaries had little immediate impact, with economic, social, and even local political relationships continuing as before. In other places, however, colonial boundaries blocked trade routes, divided tribal and even family groups, and hampered or halted patterns of nomadic and shifting agriculture. Superimposed boundaries assumed particular importance, however, when colonialism ended. Groups that had been neighbors in previous times found themselves competing for power in large states. Religious differences often compounded these conflicts.

Nigeria epitomizes the consequence of geographies inherited from the colonial era. In 2010 it was a state with 158 million inhabitants speaking some 500 languages. The northern part of the country lies within the Sahel region, and most of its people are Muslim; southern Nigerians are predominantly Christians and adherents of traditional African religions. The country's economic heartland is on its southern fringe, around the colonial era capital of Lagos and the oil-producing region of the Niger Delta. With such economic, political, and cultural divisions, it is hardly surprising that much of Nigeria's postindependence era has been marked by periods of instability and conflict.

Colonial elites also created a new geography of cities, based on colonial capitals, designed to serve as administrative and political centers as well as ports primarily for the export of local raw materials. These functions dictated their location: wherever possible, they needed to be on the coast. When west Africans had built their own cities to serve their own needs, they were located inland. When Europeans superimposed their priorities onto the landscape, coastal centers became preeminent. The map of Africa's railroads provides a further example of the new economic geography constructed by the colonists and inherited by Africans when the colonial era ended in the second half of the twentieth century (see map of Africa, 1914). Most of sub-Saharan's railroads link points in the interior to coastal ports; none (aside from those in South Africa) form a network connecting neighboring African states or even major centers within individual states.

AFRICAN COUNTRY AND TRIBAL BOUNDARIES

AFRICA, 1914

AFRICA'S RAILROADS

Northern Africa and Southwest Asia

Today the regions of northern Africa and Southwest Asia encompass all of the African countries that border the Mediterranean, the Arabian Peninsula, and those countries east to Iran. This region would have been nonsensical in early human history, when human contact encompassed smaller territories and before the major historical diffusions that define the region today—Arab traders, Islam, European imperialism, and the emergence of a world economy based on fossil fuels—happened. This region provides an example of how regions emerge historically because it includes territories that have always been central to our study of human history.

Physical Geography

This is a region bounded by a wealth of physical geographic features. It features deserts both on the Arabian Peninsula and the Sahel, which marks its southern border in Africa. It is framed by multiple seas, including the Mediterranean to the west, the Red Sea between Egypt and Arabia, the Black and Caspian seas to the north, and the Persian Gulf between Arabia and modern-day Iran. In addition, it has mountains, including the Zagros Mountains, and high plateau regions in Iran. These features have meant that there is considerable diversity in terms of the ecosystems and resources available in the region, which encouraged early trade. The physical features have also funneled trade and migration patterns, around mountains and some seas and through passes and shorter water crossings. There are multiple narrow water passageways linking larger waterways, and the control of these passageways, such as the Bosphorus or the Dardanelles, means the ability to control trade.

Not all of these routes are waterways. The Jordanian Rift Valley is a strike-slip fault zone that stretches from Syria to Mozambique. The rift had long been a north-south transportation route. In addition, it has been the site of considerable seismic activity. The Jordanian Rift Valley and the Red Sea have been caused by the divergence of the Arabian Plate and the African Plate. At the same time the Arabian Plate has been converging with the Eurasian and Anatolian plates. These convergences have resulted in mountain ranges along the boundaries of these plates and tectonic activity through Turkey and Iran. The region is, in parts, very arid. This has meant that those parts of the region that receive regular rainfall have particular advantages relative to others in the area. Those areas that could not count on regular rainfall but had rivers that could support agriculture, such as the Nile or the Tigris and Euphrates, also had relative advantages. This also means that populations have been concentrated around coasts and rivers, with the deserts supporting less dense populations. The presence of oil is central to the importance of the region in modern history. Modern uses of petroleum are typically dated to the mid-nineteenth century, shortly before European powers became increasingly interested in the area. Today, southwestern Asia remains important in global politics because of its oil resources.

Human Geography

The oldest-surviving records of agriculture are found in the region sometimes called the Fertile Crescent, located in the area of modern Syria, Israel, Turkey, eastern Iraq, and western Iran. Agricultural innovations led to increasing populations and, in some cases, population pressures. People pushed out of the Zagros Mountains by population pressures settled throughout most areas in river valleys by 4500 BCE in what is today northwestern Iraq. As the population continued to grow, people moved into new areas, including the highlands and into the Tigris and Euphrates river valleys. In the southern regions of the Tigris and Euphrates rivers, some of the first urban civilizations emerged. We can understand the question of “why there”—why this may have been the original site of civilization—in two ways. First, local conditions: the particular mix of disadvantages and advantages found in the Tigris and Euphrates rivers can be understood as producing the necessary conditions for urbanization. Alternatively, its relative location can be seen as creating the possibility for this monumental transition in how humans live.

From the first perspective, the region between the Tigris and Euphrates had been relatively lightly populated because these rivers were swampy and not prone to the regular flooding that characterized regions with easy agriculture. Unlike the regions that produced the first agricultural innovations, these alluvial plains lacked sufficient rainfall, had few game animals, and produced little usable timber. However, the area had some advantages. It had firewood, mud for bricks, fish for food, reeds for baskets, flax for textiles, and fertile soils due to flooding. Agriculture would be difficult to establish but then would be highly productive. Those settling the area had experience transforming their environments, since they probably were being pushed from the Zagros Mountains by population pressures. In their new locale, they introduced incredible innovations for managing their environment and their economy: they dug channels to direct the water, raised the ground in order to build on it, and developed dikes and basins and irrigation systems. Then they harnessed animals, used manure, rotated crops, and left some fields fallow, all significant developments in agricultural innovations. This innovation required increasing organization over labor and accounted for the emergence of groups or classes of people with considerable social power. Those who controlled the irrigation works had power and status and were able to mobilize conscripted or forced labor when it was needed. Through responding to their environment and bringing it into production, the Sumerians, who developed this area, developed the first complex society or civilization.

From the second perspective, the region between the Tigris and Euphrates had an advantageous location, close to both the Persian Gulf and the Indian Ocean and between multiple environmental regions, including the arid zone to the south, mountains to the north, and the Iranian Plateau beyond them. The diverse environments in these regions meant that people in them specialized in different kinds of products. Some historians and geographers see this relative location as the primary cause of the rise of civilization in this area. While the Mesopotamian

region had little about it in particular to explain its success, it was surrounded by places that had considerable human activity and production. As these societies accelerated trade contacts with each other, the swampy area between the rivers became an essential and vibrant trade area. Sea-based trade existed on the Indian Ocean and the Persian Gulf from before 4000 BCE. The domestication of the donkey made overland caravans possible, so trading circuits, mostly in spices and precious metals, emerged that began to integrate the peoples in the region. Later, around 200 BCE, the invention of a saddle that sat high and avoided the hump increased human's ability to use camels to transport goods long distances, and this helped further integrate the Arabian Peninsula and northern Africa.

This region was also home to some of the first empires—political systems that unite multiple cultural groups under the rule of a single emperor or governing system—in part because of the increasingly stratified societies that emerged along with more complex interventions into the natural environment. These empires differed from place to place, of course, and over time. In Egypt, for example, the Nile flooded predictably and allowed for a form of irrigation that resulted in relatively less salinization of the soil, which minimized environmental degradation. In addition, the Nile could be traveled upstream and downstream, since it flows northward and trade winds can carry boats southward, which allowed for the integration of territory through the movement of labor and goods. Predictability and integration account for the long periods in which Egypt was politically united. Other areas were less stable in their boundaries but saw the emergence of empires that expanded dramatically, integrating more territories and more people into larger scale identities. After the first millennium a series of empires, including the Achaemenid, Seleucid, Parthian, Sassanid, and Persian empires and, briefly, that of Alexander united territory stretching across much of southwestern Asia. This territory encompassed diverse populations, linguistically, and disparate environmental regions, but sporadic political unification reflected the existence of broad trade relations and other connections.

The dense population due to agricultural production and relative centrality also help explain the number of cultural phenomena that emerged from southwestern Asia. Peoples living in more concentrated groups are more likely to have the ability to produce art and philosophy. And more diverse empires also challenge earlier ways of understanding religion. While earlier religious beliefs focused on gods that represented a particular place or tribe, the development of multi-societal empires and the expansion of political power and economic interdependence led to the emergence of religious systems that were more universal. Zoroastrianism, Manichaeism, Judaism, Christianity, and Islam all emerged in southwestern Asia from either the Persian end or the Mediterranean. These new religions delinked gods from geography, liberating spiritual authority from the limits of place. The relative location of the region also helped some of these belief systems extend dramatically but usually with the help of a political entity. The Roman empire, with its exten-

sive road system, facilitated the spread of Christianity throughout the region and into Europe.

Beginning in the seventh century, Islam had unified the Arabs into a powerful force who, in turn, began an astonishing military expansion shortly after Muhammad's death in 632. By 711, the Islamic empire united an area that stretched from the Iberian Peninsula in the West to Sind, around the Indus River valley, in the East. Even after the political fragmentation of the early Islamic empires, trade connections continued the expansion of Islam. This unification and the extension of trade routes beyond these borders made it possible for a vast number of technologies and resources to diffuse throughout the territory. Papermaking, developed by the Chinese, spread through the Islamic empire, bringing with it greater literacy and a respect for the printed word. Fruits and vegetables from India were introduced to areas to the east and became the foundations of much of what we think of as traditional foods from the Mediterranean, such as spinach and eggplant. In addition, new modes of agriculture diffused throughout the region. These more intensive modifications of the environment increased production and supported larger populations. Arabic, the language, did not diffuse as broadly as Islam, the religion, so in the end it was faith that provided the common element that created the region that we recognize today. Islam is the central characteristic of the region, tying together people across ethnic backgrounds (Arabs, Persians, Aryans, Berbers, Turks, and many others), across linguistic divides, and across vastly different environments. However, Islam unites a much larger area than that which is understood as the Middle East or northern Africa and southwestern Asia, extending into Bangladesh and as far as distant Indonesia. While religion is certainly one of the commonalities that defines the region, it is not the only feature that defines the boundaries or limits of the region. The limits of the region also reflect political history. The region has been loosely united by different empires intermittently, but nation-state boundaries were established under European colonial control.

Southern Asia

Southern Asia includes India, Pakistan, Bangladesh, Afghanistan, Nepal, Bhutan, the Maldives, and Sri Lanka and is defined by its physical geography, particularly the tectonic and topographic realities that stem from the past and present movement of the Indian Plate and, at least the core of the region, by the history of British colonial rule. The region is densely populated, although unevenly so. India is the second most populous nation in the world, with a density of 850 people per square mile, while the Himalayan states have population densities just over half that. This is also a region of considerable religious and ethnic diversity. India is the hearth area of Hinduism and Buddhism, and the region also has substantial Muslim populations. The region is significant because of its growing populations, the current emergence of India as an economic contender as its educated middle class expands and as comparatively

low wages makes Indian workers highly competitive actors in the global economy, and the religious and ethnic tensions that now take on global significance. India and Pakistan, separated in 1947, have a history of constant animosity and warfare throughout their short existence and are both now armed with nuclear weapons. Both are also the focus of international interest as possible havens or targets of terrorist activities. This confluence—the presence of both fearsome weapons and people bent on violence—arouses considerable international concern.

Physical Geography

The physical geography of this region is most defined by its tectonic situation and by the monsoons that provide it with seasonal rainfall. The Indian Plate collided with the main Eurasian Plate over 50 million years ago and continues to move, slowly, today. This movement has created the boundaries of the region, pushing up the Himalayas to the north and northeast. This is the highest mountain range in the world and features dramatically diverse ecologies as one moves up in altitude. The higher areas are dramatically snowy and cold. Much of the rest of the Indian Plate is defined by the rivers that come out of the Himalayas, the Indus, and Ganges. The floodplains of these rivers have supported the most densely populated parts of the region—northern India, southern Pakistan, and Bangladesh—because of the richly fertile soil associated with them. Southern India is a high plateau fed by different rivers and is tropical in its climate.

Because it rests on a separate plate (or on the borders of two plates), the region frequently suffers seismic activity and is vulnerable to earthquakes and tsunamis, the huge waves that can result from earthquakes in the seafloor. Populations are very vulnerable to disasters due to the low average incomes, the challenging topography that makes rescue difficult, and the limited governmental capacity of some (though not all) countries in the region.

Parts of the region are defined by their monsoon climate, which still shapes the daily lives of residents and long shaped the patterns of long-distance trade in Eurasia. Monsoons are winds that flow in one direction one part of the year and then reverse for the rest of the year. The term “monsoon season” refers to the period of heavy rains that are brought by winds blowing from the southwest into the coastal part of southern Asia. The monsoon season brings the vast majority of the annual rainfall to the region, and thus agriculture is highly dependent on it. Heavy monsoons flood out coastal cities and villages, while weak monsoons put the nutritional and economic welfare of vast populations at risk. In addition to shaping how people live, the monsoons shape another important aspect of the region. Southern Asia, especially India, has a vast coastline and has been part of sea-based trade for thousands of years, through the Arabian Sea to the west, the Indian Ocean to the south, and the Bay of Bengal to the east. The monsoons largely determined when people could travel by sea before the advent of engine-powered ships. The winds across the Indian Ocean blow to the east during the summer and early fall and to the west in the winter. This

pattern meant that several entrepôts, or trading centers, emerged where traders waited for the winds to change so that they could return home. Many of these were in southeastern Asia, near Vietnam or in Indonesia, but traders in the area all had to factor in the seasonal delays when planning how to move goods around.

Human Geography

The first wave of urbanization in southern Asia was in the Indus River valley with the emergence of what is known as the Indus Valley Civilization or the Harappan Civilization. Like other early civilizations, this one was enabled by the development of agricultural surpluses and trade opportunities. The civilization traded with Sumer, for example (see section on Northern Africa and Southwestern Asia). Little is known about the organization or demise of this civilization because archaeologists have not found any long texts to translate and because there is no evidence of tombs filled with goods, such as those found in Egypt. Thus, there is little information from which to build inferences. However, it is clear that cotton was domesticated around 2000 BCE in the Indus River valley and that cotton textiles woven and dyed in the area were sold in Mesopotamia, the Mediterranean, and Egypt. Much of the sea-based trade from the last few centuries before the Common Era relied on Malay sailors, who traveled from China to the eastern coast of Africa (see Southeast Asia). A valued commodity in this trade—spices such as pepper and, later, crystallized sugar—originated in southern Asia.

India produced more than goods that were valued throughout Asia and Europe. India also produced intellectual work that transformed worlds as it diffused, such as mathematics and spiritual studies, such as Buddhism. Buddhism spread east along the Silk Roads and still provides cultural cohesion to other regions. In southern Asia, Buddhism's hearth area, Buddhism is strongest in the Himalayan region, with large concentrations of Buddhists in Myanmar and Bhutan. There are also many Tibetan Buddhist refugees in Nepal, the birthplace of the Buddha. There are relatively few Buddhists in regions that once had many, such as the area in Pakistan once known as the Kushan empire (which extended from near the Indus River and into the Himalayan mountains). This is largely because of the importance of a later religious diffusion, that of Islam.

Islam (see section on Northern Africa and Southwestern Asia) reached Sind, a region of Pakistan around the Indus River valley, by 711. However, the progress of Islam into the heartland of India was less consistent. Some regions had well-established religious traditions in place, with relatively little interest in conversion. On the other hand, other parts of India became quite diverse religiously. Parts were ruled by Muslim leaders for many centuries to come. After the eighth century, the Muslim influence in most of the region came by way of Persian-influenced Turks rather than Arabs. Indian culture, with its strong traditions of Hinduism and Buddhism, changed Islam as much as it was changed by Islam. The synergy of the different traditions provides an example of how regional identities absorb, resist, and modify outside influences. During the Mughal

period (1526–1858), Muslims, mostly converts, made up majorities in the eastern and western parts of the region as they sought agricultural land, moving into areas that had never been heavily influenced by Hinduism. Only the area along the southwestern coast of India became Islamic through direct Arab influence. The region grew commercial quantities of spices, giving Arab traders influence in the region. When Portuguese traders arrived on the scene in the 1500s, the violent encounter was not between an exploring people (the Europeans) and an indigenous group unaware of the rest of the world. Instead, it was a meeting of two expansionist groups, one interested in accessing trade goods and the other interested in maintaining control over those goods.¹

European control or influence in the region began through the establishment (or taking) of defended port cities, so very little territory was actually under European control. In 1757 the British East India Company (EIC), a trading corporation, conquered Bengal and gained access to its vast fields of poppies. The EIC had finally found a trade item in which Chinese consumers were interested. The EIC began exporting to China a commodity that previously had limited presence in the international trading scene: opium. Opium provided British trading interests with an advantage over other Europeans, since its Indian source was close to China, which reduced transportation costs. By instituting British-defined laws such as the Doctrine of Lapse, which gave the trading company control over territories that did not have a clear heir after the death of a leader, British rule was established gradually over the region.

The legacy of British colonial rule has been much debated. The British built roads and railroads, but these were largely intended to move troops from place to place and to facilitate the export of Indian goods. Trade increased under British rule but not necessarily to the advantage of those in India, who had exported spices and cotton textiles in larger amounts long before the British arrived. Indian goods were not allowed to compete with British goods, which over time undermined those Indian industries that formerly had been strong. British-imposed taxes were high in the early 1800s but then were lowered after the Mutiny of 1858, otherwise known as the Sepoy Rebellion. From the fifteenth century onward, there had been peasants from northern areas of India, Sepoys, who made their living as mercenary warriors and had served both French and British interests at various times. By 1857 the British colonial army consisted of about 240,000 native soldiers (both Hindu and Muslim) and only about 40,000 British officers and men. The Sepoy Rebellion was rooted in growing dissatisfaction with high taxes, discrimination against Indians, and the work of proselytizing Christian missionaries. It was sparked by rumors that the cartridges used by soldiers in the army had been dipped in pig or cow fat. The rebellion also changed the nature of British rule and marked the beginning of both direct British political control and of the Indian nationalist movement that worked to end British rule. India emerged from colonial rule ready for democracy but has been plagued by religious violence that some claim is rooted in British policies of divide and rule and in European definitions of nationalism.²

The region faced droughts, destructive cyclones, and famines in the early twentieth century and then again during the Bengal famine of

1943, during which millions of people died. These environmental disasters, like most famines, were compounded and intensified by political decisions. In the early 1940s the British diverted rice from Bengal to other places, and rumors of food shortages created panic and high food prices in Bengal. These policy failures and violent massacres of civilians increased the appeal and strength of the independence movement and the Indian National Congress, a group that used civil disobedience and nonviolent protest in ways that have inspired generations of activists. This activism shaped an emerging collective consciousness, a sense of Indian identity.

During this period, Indian identity was geographically broad and included those parts of southern Asia under British control. Burma, now Myanmar, was governed as part of British India until 1937 and had a very different cultural identity even while integrated. Sri Lanka, then Ceylon, also had been governed as a separate colony from an even earlier period. Thus, both of these territories had their own sense of their colonial and postcolonial experiences. However, in other ways Indian nationalism was also understood as an expression of Hindu identity. When India gained independence in 1947, there were dramatic conflicts over what and where India would be. The British partitioned the area into India and West and East Pakistan (now Pakistan and Bangladesh). Pakistani nationalism has always been rooted in both a sense of territory and a Muslim identity. Indian nationalism continues to struggle with the question of whether it should focus on nurturing its Hindu identity or whether it is more in keeping with its commitment to democracy to encompass many religious identities.

Farther north, Afghanistan, Nepal, and Sri Lanka have cultural identities shaped in part by their mountainous terrain, which results in significant cultural variation and challenges to efforts to establish larger-scale identities. Today these areas are understood as remote, hard to reach, and underdeveloped, but it is worth noting that contemporary Afghanistan was once part of the Kushan empire and was central to trade along the Silk Roads. Today infrastructure is lacking (due to war and poverty), and the area is much less integrated into regional and global trade than it was in the past.

These divisions make it a region divided against itself more than a cohesive whole. And these divisions complicate the economic resurgence of the area once central to continental trade. India, where English continues to be a language of the educated classes, is increasingly competitive in the world economy. The ability of the rest of the region to participate as strongly in the global economy seems constrained by regional, interregional, and global conflicts.

Central Eurasia and Russia

The region of central Eurasia today is dominated by Russia, whose political territory makes up the vast majority of the region and whose political influence and domination define the boundaries of the region. In addition to Russia, the region includes the area between the Black

and Caspian seas and the nations north of Iran and Afghanistan. Politically, the region has been struggling to redefine itself after the end of the Cold War and the collapse of the Soviet Union and to answer questions about who will dominate and control resources and what kind of economic development is possible or best. Physically it is defined by its position on the interior of the continent, its fairly high latitudes, and its generally high altitudes, which include both mountain ranges and high plateaus, or steppes. Despite the varied and massive terrain, most of the region has notably cold temperatures, especially in the north. While today the region is defined primarily by Russia and its influence, it has a long and often overlooked history. Its people have been shaped by the landscape and the climate and have responded through constant innovation. However, because they were largely nomadic through much of history and thus left little in the way of architecture and other high art, they are often neglected by historians.

Physical Geography

Central Eurasia centers on the steppes, which are high plateau areas. Because it is in the center of the vast continent of Eurasia, this region relies on air masses traveling long distances from the distant seas for precipitation, which is thus fairly limited. This makes agriculture challenging; there is not enough rainfall to make agriculture easy to maintain. Growing seasons are short, drought is always a threat, and soil quality is often low and difficult to improve. However, since settled agriculture is challenging, herding animals is possible, so the region has supported many nomadic pastoralist groups. These include the reindeer herders of Siberia, the Huns and the Mongols. These (and many other) pastoralist groups have been the source of significant transportation and military innovation throughout history, since they traveled long distances on horseback and needed to be able to protect their herds. In addition, they have been important for trade due to their ability to travel long distances. A band of land in southern Russia has been used for industrial agricultural production since the time of the Soviet Union. The area around Moscow, the Russian plain, also supports farming. The eastern reaches of the region rely more on logging and hunting as well as on grazing animals, and, of course, the arctic area is mostly restricted to fishing and reindeer herding in terms of food production.

While climatologically challenging, the region does have minerals in the Ural Mountains and oil in Russia and in the Caucasus Mountains. The Ural Mountains are also important because they divide the region into distinct sections, which are united more by political will than by culture or climate. The Ural Mountains create a north-south boundary that begins just north of Kazakhstan, extending up to the arctic region. They are quite high in the north and wide in the south but are more passable in their central sections. Because of their timber and minerals, these mountains have been central to Russian industrialization for centuries. They divide the Russian plain from the low-lying plains of western Siberia and the high central Siberian plateau.

Human Geography

Pastoralists are often ignored in history books because their mobility means that they leave little behind to study: no grand buildings or long written documents. Thus, it is easy to imagine central Eurasia as an insignificant space, occasionally producing some grand, violent leader like Attila the Hun or Ghengis Khan but not really mattering until Russia colonized the area and then the Soviet Union expanded even farther. However, pastoralists not only acted as traders and transporters but also traded their own goods, including animal skins, furs, meat, and horses. So all settled civilizations engaged with pastoralists, both through warfare and through trade.

The Silk Roads cut through the Taklamakan desert, and traders relied on its peoples for safe passage, local knowledge, and access to goods. The Chinese were particularly interested in accessing horses, carpets, and furs from the pastoralists in the region. Chinese silk, of course, was in demand throughout India, Southeast Asia, and the Mediterranean. At times nomadic groups would become sufficiently interested in and proficient at trade that they would conquer territory and become leaders of kingdoms central to trade, such as the Kushan empire at the western end of the Silk Roads.

During a period of global warming from 800 to 1200, agriculture spread into much more northern parts of the hemisphere, enabling an expansion of wealth and the creativity that arises during times of relative stability. However, during this same period nomadic groups, strengthened as grasslands in the interiors of the continent received more precipitation, ended up in numerous conflicts with the settled societies on their edges. The Huns invaded the plains of the Danube River (what is now Hungary) and Europe for decades. Turks raided the northern regions of India from a nomad-ruled kingdom in Afghanistan. The Mongols finally conquered China in 1279 and then turned to Russia, where they gained control of Kiev and exacted tribute from Russian principalities. All of these are examples of central Asian militarized pastoralist groups who challenged and sometimes transformed the settled communities around them. The Mongols were often brutal warriors but provided safe conditions for traders, so during the period when territory from Kiev to Korea was controlled by the Mongols, trade was possible to an unprecedented degree. Europeans, such as Marco Polo, were able to travel to China for the first time. Economic integration and the diffusion of new ideas and technologies increased as trade flourished, but these same connections led to the rapid spread of epidemics. The Plague of the fourteenth century is thought to have started in a Mongol-controlled section of the Himalayas and then to have spread along trade routes throughout the entire continent. The Mongols themselves were particularly vulnerable because as nomads they had fewer opportunities to develop immunities to contagious diseases.

After the decline of Mongol control, Moscow emerged as a political center rather than Kiev. After the fall of Constantinople in 1453, Moscow was the center of the Eastern Orthodox Church. This ended up establishing a cultural boundary between Russia and Europe that would

continue through political divides. Ivan the Great came to the Muscovy throne in the 1400s and began to establish a sense of a Russian nation and to expand its borders. In other words, Ivan began the process of creating the modern region of Russia and central Asia through a process of expansion and consolidation.

The expansion was first into the north, which increased coastal access, and then to the Urals and into Siberia. This territory was sparsely populated, and Russians began a process of settlement, expanding their territory through relocation. By the beginning of the seventeenth century Russian villages extended hundreds of miles east of the Urals, and state-sponsored trade in furs had become quite important. The rivers of this region were key to integrating this area, since they enabled Russian settlers to travel long distances. The orientation of Russia shifted over time. While the religious institutions and political structures of Russia differed from those of Europe and much of Russia's expansion was to the east, Russia sometimes shifted its cultural emphasis toward Europe. Peter the Great built St. Petersburg on territory taken from Sweden, and moving the capital of Russia to St. Petersburg was an intentional effort to associate with the West. The city's noble families spoke French by the nineteenth century. Thus, the boundary between Europe and Russia has not been static, since Russia has expanded and acquired European territory, and the starkness of the difference between western Europe and Russia has sometimes seemed dramatic and at other times less so.

As serfdom weakened in Europe, in part because of the Black Plague, Russia's reliance on serfs increased, as did aristocratic power over them. Serf labor was central to the production of grains and cereals, which eventually were major exports for the region. In addition to increasing agricultural production, Peter also cultivated the exploitation of mineral resources. During his reign Russian minerals were surveyed and mined, a new economic development that shifted the Russian economic center toward the Ural Mountains.

During the period of European imperial expansion, Russia expanded to the south and the east and eventually reached the Bering Sea north of China. Much of the territory, such as the Khanates of Bukhara and Khiva, both east of the Caspian Sea, was established as dependent territories or vassal states, thus assuming a subordinate position to the Russian state, which was not trying to fully integrate the diverse populations. In addition, this model of expansion left in place existing political and social frameworks that allowed minority cultural identities to reproduce themselves while local elites maintained some degree of power. Russian expansion differed from European expansion in that it was directed toward contiguous territory rather than more distant regions. Theirs was a land-based imperialism as opposed to the sea-based ventures of the west European states.

The social and economic organization of Russia, which was still largely rural and was exploited at the dawn of the twentieth century, led to increasing violence by peasants against landlords and agents of the state. The increased hunger and chaos of World War I led to the collapse of the Russian tsarist government. The October Revolution of 1917

marked the establishment of the USSR. The Bolshevik leaders withdrew support from the Allies in order to try to fulfill their promise of “peace and land,” a decision that was part of the larger alienation of the Soviet Union from the capitalist countries in Europe, further defining the region as fundamentally not European. Soviet expansionism in the post-World War II period was both a response to and a contributing cause of the alienation and hostility between the Soviet world and the capitalist West. It also redrew regional boundaries for decades, as central European countries, such as the Czech Republic and Poland, were redefined as “Eastern Europe.” After the fall of the Berlin Wall and the subsequent Velvet Revolutions, these countries have reasserted their European identities, though often struggling with the development and historical legacies of decades of Soviet control.

Other nations, including those around the Black and Caspian seas, are also confronted with having to come to new understandings of themselves in the world, but they have often had a longer period of Russian control or influence. Will they remain Russian-focused or reorient themselves toward southern or southwestern Asia? Do they constitute a regional bloc with their own economic, social, and political interests, or have the centuries of Russian control established a particular continuing identity that will continue to shape the future?

Despite a relatively weak economy and shaky steps toward a representative democracy and good governance, Russia and the region that it dominates and shapes continues to have global influence, in part because of its size and history but also because of its stores of minerals and fossil fuels.

Southeast Asia

The region of Southeast Asia encompasses 11 countries and spans some 35 degrees of latitude and 50 degrees of longitude. Its 11 countries include 4 of the world’s 20 most populous—Indonesia, Philippines, Vietnam, and Thailand—and the region as a whole is home to about 8 percent of the world’s population. It is a region that 1,000 years ago was home to the one of the largest and most advanced cities in the world—Angkor—and that in the twentieth century was the scene of some conflicts of extraordinary violence, including the Vietnam War and the Cambodian Genocide. It is impossible to understand the importance of this region and the events that have taken place there without an appreciation of Southeast Asia’s human and physical geography and particularly its critical location along the sea routes linking eastern Asia with the Indian Ocean.

The region of Southeast Asia can be divided into two parts: mainland and insular Southeast Asia (see map of early empires in Southwest Asia). Five countries are located entirely on the mainland: Myanmar (Burma), Thailand, Laos, Cambodia, and Vietnam. Malaysia straddles the mainland and islands, and the remaining countries—Indonesia, the Philippines, East Timor, and Brunei—are island countries.

KINGDOMS OF SOUTHEAST ASIA, 1200–1500

Physical Geography

Insular Southeast Asia consists of an archipelago of islands ranged along two of the world's most active tectonic plate boundaries (see map of tectonic plates). Indonesia lies adjacent to the boundary between the Australian and Asian plates, and the mountains and islands of the archipelago owe their existence to the collision of these two plates. Some of the most violent volcanic eruptions in earth's history have taken place along this plate boundary. The Toba eruption, which took place some 72,000 years ago in the southeastern part of the island of Sumatra, produced so much ash and dust that it changed global climates, giving rise to a six-year ice age and devastating human and animal populations worldwide. In 1883 the eruption of Krakatoa west of the island of Java killed thousands, and in 2001 an undersea earthquake near Aceh in Sumatra caused the deaths of over 300,000 people along the coast of the Indian Ocean.

The Philippines lies alongside the Pacific Ring of Fire and is also a tectonically active area. The 1991 eruption of Mount Pinatubo caused considerable damage and also emitted a gas cloud that affected climates worldwide.

The modern landscapes of insular Southeast Asia reflect their tectonic origins. Indonesia is a mountainous country, its highest peak more than 16,400 feet (5,000 meters) above sea level, with over 400 volcanoes, about a quarter of them active. Volcanic ash has produced fertile soils, which are often found in places that are both mountainous and densely populated. The islands of Java, Madura, and Bali, comprising 6.9 percent of the land area of Indonesia, were in 1980 home to some 64 percent of Indonesia's population, necessitating the intensive use of agricultural land.

The topography of mainland Southeast Asia has also been significant in the region's history. The region is bounded to the north by the formidable Himalayan mountains, a daunting barrier to travel and trade. Extending through the peninsula are a number of smaller mountain ranges, separated by river valleys that have been important to civilization and trade throughout the region's history. Most important among these is the Mekong, a transportation route and source of sustenance and an avenue of trade for peoples of Laos, Cambodia, Thailand, and the southern part of Vietnam. Three modern national capitals—Vientian, Phnom Penh, and Ho Chi Minh City—lie on or close to the Mekong. The Irrawaddy River has long been the focus of Burmese civilization and commerce. The precolonial centers of Pagan and Mandalay are on its banks, and the modern capital of Yangon is located at its mouth. Other important rivers in the region are the Chao Phraya, which flows through the Thai capital, Bangkok, and the Red River, along whose lower reaches lie one of Vietnam's important rice-producing areas, as well as that country's capital, Hanoi.

While river valleys have historically made up the political, economic, and demographic cores of mainland Southeast Asia, mountain and upland regions make up the periphery. In Vietnam, Laos, Thailand, and,

TECTONIC PLATES, WORLDWIDE

most of all, Myanmar, members of the so-called Hill Tribes—among them such groups as the Karen and the Hmong—are among the region's most marginalized and disenfranchised peoples.

Most of Southeast Asia lies within the tropics, but its climates show considerable variation. Tropical rain forest and monsoon climates cover most of the area, helping to account for the agricultural abundance of much of the region and in particular its ability to produce tropical crops and rice, staples of the region now as in the past.

The monsoonal climates of western Southeast Asia have affected not only agriculture but also trade (see climate map). Monsoons are winds that reverse their flow seasonally, blowing from the west during the summer monsoon season and from the northeast during the winter monsoon season. In the era of sailing ships, this facilitated trade between southern Asia and Southeast Asia. It also contributed to the rise of the port city of Malacca, a destination for seafaring traders and a place where sailors would await the reversal of the winds for the journey west.

It is important to note that physical geographies of the region have changed over time and that their changes have had an important impact in and beyond the region. Early humans passed through Southeast Asia between 60,000 and 50,000 years ago on their way to Australia. At that time global climates were cooler and sea levels lower, allowing a mostly land-based journey from Asia to Australia. During the last ice age, some 20,000 years ago, sea levels were even lower, linking or narrowing straits between parts of the Southeast Asian archipelago that are now separated by oceans.

Human Geography

The human geography of Southeast Asia is in large part a reflection of the region's location and its physical geography. Located astride the searoutes linking eastern and southern Asia, the region long interacted with both of these regions. Location made parts of the region an early focus of European trade and colonialism and also contributed to the area's strategic importance to the major powers during and after the Second World War (an importance that had violent and tragic consequences for several countries in the region).

Broadly speaking, the western parts of Southeast Asia had the most interaction with areas to their west, the eastern part with areas to the east, and the coastal areas of insular Southeast Asia with both. And the optimum locations for interaction in all directions, those along the Strait of Malacca, have been able best to capitalize on the region's strategic location. Vietnam's history has long been closely (although not always harmoniously) linked with that of China, Burma's with India, and the littoral areas of insular Southeast Asia with each other as well as with traders and colonists from as far afield as Europe and Japan. Separated from the rest of mainland Southeast Asia by the Annamite Ranges, Vietnam historically had more interaction with China than with its neighbors to the west. The architecture, the imperial form of government,

Chinese variants of Buddhism, and the rendering of the Vietnamese language using a Chinese writing system were marks of this legacy. With the arrival of European influences in the area, however, came a change in some parts of the cultural landscape, most notably with the replacement of Chinese characters with a Romanized alphabet in written Vietnamese. Outside cultural influences vary regionally in Vietnam; for instance, Chinese influence dominated North Vietnam to a much greater extent than occurred in South Vietnam. The cultural landscape of western mainland Southeast Asia, west of the Annamite Ranges, carries the imprint of a long history of Indian influence: in writing systems that trace their origins to Sanskrit, in temples honoring Hindu gods, and perhaps most notably today in the prevalence of Buddhism, which superseded Hinduism in Thailand, Cambodia, Laos, and Myanmar.

The same trade routes and strategic location that brought outside influences to Southeast Asia at times also helped the region to project its own power and influence. The kingdom of Srivijaya (about the fifth to fourteenth centuries) capitalized on its location in southern Sumatra to control much of insular Southeast Asia (see map). And Southeast Asia—both islands and the mainland—were not simply the passive recipients of outside influences. Local populations adopted ideas that they learned from outsiders, but they also adapted them to their own needs and exported their own ideas. Hinduism came to mainland Southeast Asia, for example, but the caste system did not. Wet rice cultivation was a Southeast Asian innovation and diffused outward to other parts of the world.

Paradoxically, perhaps, one of Southeast Asia's largest and most powerful kingdoms seems to have eschewed the locational advantages of a coastal area in favor of a less accessible inland location. The capital of the Angkor kingdom was located on the flat and fertile lands at the northern end of the Tonle Sap, Cambodia's Great Lake, and Angkor's control extended through much of mainland Southeast Asia (see map). Angkor was a society of remarkable technological, agricultural, and architectural sophistication, and at its peak in the fourteenth century its capital was home to over 1 million people, making it one of the largest cities in the world.

Insular Southeast Asia

The location of insular Southeast Asia provided a different, though overlapping, set of influences from those experienced on the mainland. The littoral parts of the region have some of the longest histories of outside contact and influence in Asia. The Strait of Malacca, the most important sea link between the South China Sea and the Indian Ocean, has long been a highway of trade. Today, the clearest evidence of this is the city-state of Singapore, whose resource-poor but thriving economy owes its existence largely to its economically advantageous location at the southern end of the Strait of Malacca. Just to the north, the city of Malacca served as a port for Chinese traders and later for the Portuguese, Dutch, and British. The island of Penang, at the northern end of the strait, is

now being promoted by the Malaysian government as a manufacturing and trade center in part on the basis of its pivotal location.

The cultural and economic geographies of the Indonesian and Philippine archipelagos also reflect the area's location, but the effect differs profoundly depending on whether its society occupies a littoral or an inland area. Coastal regions have a long history of contact with outsiders and modern evidence to show for it. Most notable is the influence of Islam, which arrived in the area with Arab traders and was firmly established by the fifteenth century. Indonesia today has the largest Muslim-majority population in the world. Islam is also the predominant religion in Malaysia and Brunei. Insular Southeast Asia was also the earliest focus of European trade. The tropical climates and accessibility of the Spice Islands (in the modern-day Maluku) attracted European traders in the sixteenth century and later colonization by the Dutch (in Indonesia), Spanish (in the Philippines), and the Portuguese (in East Timor).

If accessibility and strategic location characterize the coastal areas of insular Southeast Asia, inaccessibility marks the inland areas. Mountainous terrain and tropical rain forests make the interior parts of islands like Borneo and New Guinea some of the least accessible places outside the polar regions. Their human landscapes reflect this: indigenous religions and languages predominate, populations are overwhelmingly rural, and subsistence agriculture as well as hunting and gathering are the mainstays for much of the population. The cultures of these areas are also some of the most diverse in the world. Inhabitants of the island of New Guinea alone speak over 1,000 languages.

Eastern Asia

Eastern Asia includes China, Taiwan, Hong Kong, Macau, North and South Korea, and Japan. Mongolia and Vietnam have also been closely tied to the region, while both have close connections that generally associate them with other regions. China's cultural, political, and economic influence in the region is long-standing. The recent economic rise of China can be understood as either a modern industrialized emergence or as a reemergence of a historic hegemon. China's vast territory, diverse resources, and large population allowed it to produce many of the most desired luxury goods of the classical era and all eras since. Japan rose as an economic power in the late twentieth century, but we would be myopic to imagine that the east Asian region has not played an important economic role in the world before. Korea has long had a sense of separateness but has spent more than 2,000 years resisting annexation primarily by the Chinese but also by the Japanese, primarily since the late nineteenth century.

Physical Geography

The continental core of eastern Asia is a vast area that encompasses dramatically different environments. The region has a very long coastline,

bounded on the east by the Yellow Sea and Pacific Ocean and on the south by the South China Sea. To the north are a series of deserts, including the Gobi and Ordos, and to the northwest are very high mountains. These geographic barriers largely define the boundaries of the east Asian region as well as the Han cultural region. The eastern section is defined by three river valleys. The Huang He, or Yellow River, to the north (also the hearth area of Chinese society); the Yangzi River to the south; and then the His River, farther south, that runs into what are today some of the largest and most important areas of China, including Hong Kong. The region also includes Korea, the islands of Japan, and the island of Taiwan, off the southeastern coast of China. This physical context has long shaped the historical geography of the region. Much of the early history of the region was marked by the expansion of Han culture and political control from north to south and the emergence and consolidation of a coherent and cohesive identity throughout the territory through migration and colonization. Even during this process of expansion and consolidation there has also been a long-standing relationship between China and its neighbors to the north. The Great Wall of China, for example, is a monument to long-term tensions between the Chinese and the nomadic peoples to the north. The wall is a cultural marker, obviously, but it follows a division that is both political and physical, reinforcing the boundaries of the region.

The region is rich in resources, which have supported considerable populations for millennia and account for the rich history of the area. The low-lying areas in the mainland have long been used for agriculture, and dense populations have been able to develop because of the richness of the soil. The mountain ranges are the source of rivers that support those agricultural plains but also have deposits of coal, oil, and other mineral resources. The mainland region is divided by east-west-running mountain ranges including the Qinling mountains, which mark a division between environmental and cultural subregions.

China has been a major cultural influence in the region, but the other areas should also be understood independently. Japan consists of four main islands: Honshu, Kyushu, Shikoku, and Hokkaido. Japan's history has been shaped by its island status, divided from the mainland and tied to the sea. The southern part of the island of Honshu has the best agricultural conditions, and early populations concentrated there. Obviously, fishing has also been an important resource for the island. The relative isolation that comes from being an island also contributed to a strong sense of Japanese nationalism; while there were always ties to the rest of the world, the seas protected Japan from all but the most determined invaders and gave the Japanese a strong sense of their own identity and power. Japan was originally populated by people from the Korean mainland. Korea, a peninsula that drops off of the mainland and toward Japan, appearing on the map rather like a finger pointing from mainland eastern Asia toward Japan, is separated from China by the Yellow Sea and from Japan by the ocean. Its relative location is an important feature of its geography and accounts for the its neighbors' intense interest. The climate of the region is extremely diverse, ranging from tropical in the south to almost arctic in the north. What makes eastern

Asia a region is not climate or environment but rather political and cultural connections.

Human Geography

The human geography of the region begins with an understanding of how human activities increasingly shaped the diverse physical geography of China, mostly in order to integrate disparate peoples into a single and more or less unified cultural, economic, and political region. China has been the central political and cultural actor in eastern Asia throughout recorded history, although Japan and Korea have developed distinctive cultures and at times have been actors in the world political arena as well.

Agriculture began with the cultivation of millet around the Hwang He as long as 9,000 years ago. Winds off the Gobi desert deposit fertile loess soil in this area. Agriculture supported the emergence of villages, but many of these villages remained seasonally mobile until the introduction of rice from the south about 5,000 years ago. From this period, there were well-established villages and signs of craft specialization and increasing social stratification. The emergence of what would be a Han-dominated region, however, can be understood as coming from the creation of coalitions among the walled villages of northern China. These coalitions facilitated the diffusion of what would come to be seen as traditional Han culture, including the cultivation of silkworms and the worship of ancestors. These coalitions shifted over time, with different clans or dynasties asserting control over generally broadening territory. Almost always, the coalitions were organized in order to fend off threats from militarized nomadic pastoralists to the north and to facilitate the development of infrastructure necessary to increase agricultural production.

The shift to more intensive agriculture included increasingly greater interventions into the natural environment. Toward its southern end, the Huang He was contained between levees and eventually flowed at aboveground level, a dramatic example of human intervention into the environment. More dikes and canals were developed in order to maximize agricultural production by controlling floods but also to provide the means for greater social and political control by creating transportation networks. The growth of agriculture and the expansion of populations also facilitated the shift of populations and production to the south around the Yangzi River valley, which was better suited to rice production. The desire to maintain political control and to integrate the north and south led to the development of larger-scale canals including the Grand Canal, which was completed in 611 CE. The Grand Canal connected the Huang He and the Yangzi River, facilitating trade, tax collection, and the movement of troops to the northern frontier, a perennial problem for China. In the early 1400s the second Ming emperor, Yongle, renovated the 1,200-mile canal as a centerpiece of his efforts to establish himself as a great leader. Thus, the boundaries of the region are defined by mountains and deserts, but the inside of the region has long been integrated to a remarkable degree through canals and public works projects.

Much of Chinese art and philosophy emphasized the importance of the environment through landscape portraits and through the development of a set of ideas that linked good governance and good living to patterns in nature and the overarching order of the cosmos. Cities were organized into nine sectors, with the homes of elites in the center. Cities themselves were (ideally, theoretically) the center of a similarly patterned set of fields (since agriculture was necessary to support urban life), which reflected the order of the Chinese lands that in turn reflected the organization of the cosmos. While China did not produce universal religions such as Christianity or Islam with an omnipotent god, the Chinese believed in an ordered universe that provided guidance for appropriate behavior. These philosophies relied on metaphors about nature, which was seen as a meaning-laden realm.

Confucianism, in one form or another, spread across the region, as did other aspects of Chinese culture. Although there have long been cultural and economic ties throughout the region, societies have kept a very distinct sense of identity. Korea is an excellent example of the individuality maintained by societies even though often in the shadow of stronger powers. Both China and Japan have had ambitions regarding Korea, and both have conquered and governed the peninsula on occasion. China considered Korea a client state through most of its history, recognizing its independence in 1895, which inspired another effort by the Japanese to annex the state. Taiwan was a contact area: the Portuguese landed there in 1544, the Dutch established a base in 1624, and it has been an area frequently contested by various states throughout the subsequent centuries. Japan itself practiced fairly isolationist policies from the seventeenth century to the nineteenth century and, like China, had a predominantly agricultural economy. Despite population pressures, Japanese urbanization had not been as extensive as in Europe and faced the same fuel depletion issues that Britain had (see section on Europe). Beginning in the mid-nineteenth century, Japan recognized the threat to its independence posed by strong European and North American economic and industrial interests and began to develop industries and invest in its military. Japan also began a period of imperial expansion, gaining territory throughout eastern and Southeast Asia, including Vietnam, Korea, and Manchuria. While Japan experienced devastating losses in World War II, including nuclear bombs being dropped on its cities, the country emerged from the postwar era as a strong industrial power.

Japan seemed for a while to be destined to be a truly modern society surrounded by countries not thriving to the same degree. But the successes of the “Asian Tigers”—Hong Kong, Taiwan, Singapore, and South Korea—as well as the rise of China as a major economic player in the world market suggests that the characteristics that long made eastern Asia a center of cultural and economic production remain important. The large populations and diverse natural resources contribute to impressively high productivity but have resulted in some rather severe environmental problems. Nevertheless, the economic ingenuity of the Japanese emerged from a history of skillful adaptation.

Europe

Europe makes up the western peninsula of the Eurasian landmass. The commonalities that help constitute it as a cultural region include religion and a collective racial identity formed through the experience of exploration and colonialism, and, in the modern era, economic strength based on industrialization. Much of Europe (but not all) was part of the Roman empire, but even those areas that lay outside the empire tend to include it in their heritage in one fashion or another. The physical boundaries of the region include the Atlantic to the west, the Mediterranean to the south, and, traditionally, the Ural Mountains to the east. The Ural Mountains are in Russia, which is sometimes identified as European, and does share some heritage with Europe. However, Russian culture is distinct enough to constitute the heart of another region entirely. Membership in the European Union (EU), which includes 27 countries, might also be considered a marker but is a very imperfect indicator at best. The EU does not include Switzerland, which is located in the center of Europe, or Norway, which is located in the far northwest and cannot plausibly be part of any other region. Serbia, Bosnia and Herzegovina, and Croatia are not members of the EU either, although Bulgaria, Greece, and Romania, located farther east, are members. Being European can carry a set of privileges, including academic and economic access and ease of movement from one state to another, yet the economic, religious, cultural, and historical criteria that might be used to define Europe are explicitly contested. Europe is as difficult a region to define as any other.

Physical Geography

Europe's topography is quite varied, but it is more mountainous in the southern regions and more characterized by plains in the northern parts. North of the Alpine mountain chain, the soil is fertile and productive for agriculture, although the Nordic countries of Europe have short growing seasons due to the cold. The climate of most of Europe is warmed by ocean currents off of the Atlantic, and temperatures in general are higher than in other areas at the same latitude.

Europe's coastline is uneven, which results in a long coastline relative to its area. Many European countries have been involved in maritime innovation and exploration. This is clearly true for the Vikings in the north and the early Greeks and eventually for the Spanish, Portuguese, Dutch, British, and French. However, many other European countries are landlocked, so a nautical tradition should not be imagined as a universal European experience.

If one considers connections and interactions as defining regions rather than just culture and continuity, European countries that border on the Mediterranean Sea have long participated in a set of economic, cultural, and philosophical exchanges around that body of water. While today we tend to see Europe as a distinct territory and the Mediterranean as dividing Europe from northern Africa and southwestern Asia,

traditionally these areas have been linked. The distance from the Iberian Peninsula to the northern coast of Africa is easily traversed. The Roman empire included territory on all sides of the Mediterranean, so while it was central to the formation of European identity, it formed that identity in relation to other regions in the world.

Human Geography

Many Europeans consider Ancient Greece the birthplace of Western civilization and the values of democracy and individualism. The weight of this philosophical tradition is one element that explains why Greece, which is fairly far to the east, is generally understood by Europeans as part of Europe (although some Middle Easterners consider it part of western Asia), even though its economic development lags behind the rest of the region. The Greeks divided the world into three regions: Europe, Asia, and Libya (Africa). These were the regions that the Greeks saw as surrounding them, and they would not have described themselves as belonging to any of them.

The Roman empire brought much, though not all, of Europe into a larger world for the first time and provided European elites access to elite goods produced throughout the rest of the hemisphere. The Roman empire integrated considerable territory by building roads, infrastructure in cities, ports, and harbors, and other investments that supported trade and bureaucratic control. Those areas not under direct Roman control (mainland Europe north of the Danube River for the most part) but close to the empire were also transformed by Roman influence. There was a great deal of trade as well as considerable conflict between Germanic tribes to the north and the Roman empire. The administrative burden of governing a huge territory led to the division of the Roman empire into two sections at the end of the third century BCE, and the eastern portion survived until the fifteenth century. In the West, failing trade policies, military losses, and the arrival of a militarized nomadic group, the Huns, from the central Eurasian steppes destabilized the northwestern frontier. While many members of Germanic tribes had assimilated into the Roman empire and fought in the military, the threat of the Huns increased attacks on the Romans and led to many “barbarians” seeking refuge from the Huns in the Roman empire. As today, refugees lived in poor conditions and threatened the social stability in the host domains. Romanized Europeans worried about the degree to which Germanic groups could assimilate and be more loyal to the empire than to their tribe. In other words, immigration issues arose.³ Gradually, the western political organization crumbled; the last Roman emperor was deposed in 476. As the Roman empire lost its ability to manage the western half of its territory, leadership fell to the Germanic chiefs. These new leaders did not have the advantages of a large empire and had to find other ways to appeal to local elites. Eventually, national identities provided a way of uniting and assimilating the populations of territories. By the nineteenth century, nationalism became one of the central dividing and unifying features of European culture.

The Iberian Peninsula was conquered by the Islamic Umayyad dynasty in 711; by 738, their campaigns reached far into France. Although they were pushed from France, the experience inflamed European animosity toward Muslims, which the erstwhile Iberian aristocrats who had been pushed to the Pyrenees constantly reinforced. The proximity with conquering Muslims intensified fundamentalism in both groups. Medieval European Christian aristocrats developed a warrior mentality and a rejection of all matters associated with “infidels.” Tensions between the Muslims and Christians took on the character of religious conflicts. From the seventh century, European Christians warred with Muslims in an attempt to reclaim the conquered Christian lands of Iberia; the island of Sicily was firmly in Muslim hands by 965. In 1074 the eastern emperor, Michael VII, appealed to Pope Gregory VII for help in repelling advances into the Byzantine empire. Pope Urban II, Gregory’s successor, called a council in 1095, stressing the plight of Christians in eastern areas and launching the first Crusade against Islam. Over the next century, these efforts of Western Christendom had the effect of giving some area of unity to the feuding Germanic princes of Europe.

The conflicts also increased contact (as well as mistrust and ill will) between Europeans and non-Christian populations in southwestern, southern, and western Asia. Through this contact, Europeans began to learn about scientific and medical traditions developed throughout the Islamic world. Exposure to the wealth and highly organized states of the Islamic lands transformed European culture, even as it intensified anti-Islamic sentiment. The Crusades actually increased trade as Europeans gained access to goods from the rest of the Eurasian landmass. Mongol rule provided safe passage for traders throughout the thirteenth century, and Europeans gained substantial experience in long-distance trade and the financial skills that facilitated it; unfortunately, they also came into contact with deadly pathogens. Bubonic plague spread along the trade routes during the fourteenth century, killing one-third to one-half of infected populations across the Eurasian landmass. One result of the Black Death in Europe was to create a new independence among peasants on continental Europe who gained new power to negotiate terms in exchange for their labor. On the other hand, in the British Isles, many landowners discovered that they could earn a greater return by expelling peasants and raising sheep for wool.

The rise of Europe is less mysterious and miraculous when understood within the context of this earlier period of trade and contact, during which Europeans learned much of the science, philosophy, and banking from sophisticated Indians and Arabs that encouraged them to develop market economies. After the demise of the Mongol empires, the Age of Exploration began as Europeans sought access to these goods by developing new routes that could avoid having to confront the Islamic Ottoman empire and other impediments. European exploration should be understood as motivated by a search for wealth and trading opportunities rather than just an interest in the unknown and undiscovered.

European exploration intensified by the mid-fifteenth century and slowly but surely transformed most of the globe, particularly Europe

itself. Exploration and colonization gave Europeans access to resources and led to dramatic transformations in production and trade. The emergence of sugar plantations in the Atlantic fueled the slave trade and led to a new protoindustrial form of production that was highly regimented, dependent on considerable amounts of machinery, and based entirely on long-distance trade. These experiences were central to the later emergence of industrial production within Europe. In addition, the increase in trade led to new roles for states in Europe. Governments increasingly invested in infrastructure to help trade in the sense of both transportation and investment. Ports, canals, and roads were developed. At the same time, governments became more adept at collecting taxes and regulating economic activity. All of these were capacities that helped Europe emerge as politically and economically strong in the coming age. Other changes followed. Colonialism, the slave trade, and global trade in general transformed power within Europe as new classes of people prospered. Their newfound wealth did not immediately translate into political power, which resided in the hands of monarchs and an aristocracy. Increasingly, kings made common cause with merchants and explorers seeking improved access to markets, challenging the traditional military aristocracy. The gradual realignment of power inspired new ideas about power and legitimacy. Instead of divine right (or military might) being the sole source of political legitimacy, a social contract between government and the people gradually became understood as the source of political legitimacy. Over subsequent centuries the boundaries between subject and citizen had been challenged, but this understanding of popular consent has become a central understanding of political organization in Europe and elsewhere.

Modern industrialization originated in Great Britain, but the techniques spread rapidly. The British had been exporting woollens for many years, and entrepreneurs were searching for more efficiencies in production. After centuries of cutting down forests, Britain faced a fuel shortage and needed to develop alternative forms of energy. In addition, Britain had coal deposits that could be used to meet those needs. Other characteristics that made industrialization possible were more broadly distributed, including surplus labor and capital to invest in new forms of production. But it is also important to realize that some of the features that enabled industrialization came from the contacts with the rest of the world that were reshaping Europe. From the fifteenth century, Muslims were establishing commercial plantations in Africa and nearby islands. Europeans colonizing the New World adopted the model and reworked the efficiencies of plantation-style production for other kinds of production. Knowledge about Indian cotton production was imported and modified. Industrialization, like capitalism, did not spring full-grown from European soil but instead emerged through interactions with other groups and regions also experimenting with new ways of producing goods and organizing economic relationships.

In the early twenty-first century, despite the creation of the EU, Europe's political geography remains somewhat fragmented into relatively small and numerous political units, often defined by a strong sense of nationalism. In the twentieth century this led to two major wars, and

since then there has been an increasing effort to shape a regional or European identity (in part to be able to compete with the United States economically in the world economy). Since the end of the Cold War and the collapse of the Soviet Union, Europe has seen the intensification of these seemingly opposite political trends. On the one hand, countries have divided, peacefully or violently, over nationalist differences, while on the other hand, the EU has gained strength and numbers. The increasing role of a European identity rather than a collection of disparate national identities has been complicated by large numbers of immigrants coming from Africa, the Middle East, and southern Asia. All regions grapple with issues of identity, but the relative power of Europe in shaping the modern world means that Europeans have the power to define their own region and other regions. Europeans have defined Europe through a set of ideas and values. Resistance to immigration and anxiety about protecting borders and resources mean that Europeans are struggling to understand what characteristics are necessary for an entity to be classified as European. Should it be commitments to abstract and universal principles, such as individualism, democracy, and free trade, or less universal things like birth, race, or religion?

Regions of the Americas

Scholars are still uncertain about the number of waves of prehistoric migrations into the Americas. The first was probably about 35,000 years before the present. But genetic and linguistic evidence suggests several subsequent migrations, taking place during times when global temperatures were colder and sea levels lower than they are today and when Siberia and Alaska were linked by an area of unbroken land known as Beringia (see map of ice ages and land bridges). These early migrants were the ancestors of a wide variety of indigenous American peoples living in areas as diverse as the Amazonian rain forest, the islands of the Caribbean, and the plains of North America.

The perception of “America” and how the word is used differs in various parts of the region today. Physiographically, the Americas are a contiguous landmass reaching from the Aleutians in the north southward to Cape Horn (but for the artificial and very modern division of the Panama Canal). This, however, treats as homogenous a territory that encompasses vast differences of climate, topography, and culture. On the basis of physical geography, the Americas can be divided into North America and South America, connecting at the southern end of Panama. Cultural and economic geography, however, argue for treating wealthy and developed Canada and the United States separately from the hemispheric neighbors and distinguishing between Anglo-America and Latin America. This division may make economic sense but is simplistic both as a cultural notion and physiographically. Culturally, it ignores in “Latin America” the numerous non-Latin peoples, including indigenous Americans, millions of Americans of African descent in the Caribbean basin and Brazil, and the non-Latin European cultural legacy found in places such as Jamaica, Haiti, and Aruba. Similarly, the

term “Anglo-America” ignores indigenous Americans, African Americans, Francophone Canadians, and Asians and the complex of immigrants throughout North America. Physiographically, the term lumps together a vast diversity of climates, topographies, mainlands, and islands.

Another way to conceive the Americas is as three distinct but related regions. North America, with the dominant population having roots in western Europe, consists of the economically powerful geographic north, Canada and the United States of America. Central America, including for our purposes Costa Rica, El Salvador, Guatemala, Honduras, Nicaragua, Panama, Mexico (despite its location on the North American continent), and the islands of the Caribbean—the most populous of which are the Bahamas, Cuba, Jamaica, Haiti, the Dominican Republic, and Puerto Rico. The third district, South America, consists of the 13 countries of the South American continent (Colombia, which used to include Panama, and Venezuela, Guyana, Suriname, French Guiana, Brazil, Uruguay, Argentina, Chile, Peru, Ecuador, Bolivia, and Paraguay). Central and South America have cultural roots that combine Iberian influences with indigenous traditions.

North America

The region we are herein designating “North America” consists of only two nation-states, the United States and Canada. These countries are both wealthy and are economically intertwined, share common demographic and cultural characteristics, and have similar histories of early settlement, European colonization, and early industrialization. Despite these similarities, however, the case for defining the region of North America, as with all world regions, is problematic.

From the perspective of physical geography, if North America is indeed a region, it includes the landmass atop the North American plate and stretches from Canada’s northernmost Arctic islands as far south as Colombia’s northern border, including the Caribbean islands of Cuba and Hispaniola (see map of tectonic plates). If the region were to be defined based on its history and current cultural geography, much of the southwestern United States would have to be included in the same region as Mexico, the erstwhile political authority in the area and a country with whom a plurality of its population share a language and cultural heritage. The economies of North and Central America are closely linked by trade as well as migration, both legal and illegal. Politically, U.S. hegemony in the region dates back to the Monroe Doctrine in 1823, which was a declaration that the United States would consider any European efforts to colonize or interfere in the affairs of any region of the Americas to be an act of aggression. North America exists as a separate region largely determined by economic and cultural factors. The United States and Canada are stronger economically and share culture derived largely from western Europe; however, it should be stressed that there is a strong blurring along the borderlands of Texas, New Mexico, Arizona, and California, where the Spanish language and Hispanic culture are well established and growing.

Physical Geography

North America is a large region: Canada is the world's second-largest country, and the United States is the third-largest country. Together they have a land area of 7.65 million square miles, about 2.5 times the size of Australia or two-thirds as large as Africa. North America's physical geographies are diverse, ranging from vast plains to high mountains and from subtropical grasslands to tundra.

It is impossible to understand the history of the region without an appreciation of the opportunities provided by the physical landscape and the ecosystems it has supported. Climate, soils, and surface water made large parts of the region suitable for agriculture from precolonial times onward. Neolithic hunters who settled the southwest found environments that encouraged the development of agriculture. The coastal plains of the southeast proved suitable for plantation agriculture, particularly cotton. The lowlands of the continental interior were ideal for wheat and corn, and the advent of mechanized agriculture was made easier by large expanses of flatland. The Pacific climates of northern California provided an ideal environment for growing fruits and vegetables, and aided by irrigation schemes, the central valley of California was made into one of the world's most successful fruit- and vegetable-producing regions. Forests, first naturally occurring and later planted, provided an ample supply of wood for fuel, boatbuilding, and construction.

The physical environment also proved a boon to the development of transportation systems. The Mississippi-Missouri river system is the world's largest navigable river system, the Great Lakes provided another extensive array of trade and transportation routes, and the navigable rivers of the eastern seaboard proved invaluable in the growth of cities from Montreal to New York and Baltimore. Technology surmounted some of the obstacles that nature had provided: the Erie Canal linked the Great Lakes with the Hudson River and New York, and locks and canals linked the Great Lakes to the St. Lawrence and the Atlantic and helped facilitate trade from New Orleans to St. Paul and Pittsburgh.

North America's mineral deposits provided many of the resources necessary to support the Industrial Revolution and its aftermath. Extensive coalfields in the Appalachians and iron ore deposits in the Great Lakes region fueled the rise of the steel industry (navigable waterways played a role here too). Extensive coalfields in the Great Plains have supported the generation of abundant supplies of electricity enhanced by large public works projects such as the Hoover Dam and the dynamos installed at Niagara Falls. Oil and natural gas have also been important resources in the region, particularly in the Gulf of Mexico, Texas, California, Alaska, and the Great Plains of Canada.

The location of North America, separated from Europe and Asia by large oceans or desolate polar climates, has also had an impact on the region's history, inhibiting outside invasion, refugee movements, or political confrontations to the degree that have marked the histories of Europe, for example, or Southeast Asia. Despite manifold natural resources, it is worth noting that most of North America is not fecund: most of Canada and Alaska lie within Arctic or subarctic climatic regions

and are entirely unsuitable for agriculture (although these regions have historically provided a home for small populations of indigenous peoples relying on hunting and fishing). Some of the region's richest mineral deposits lie in remote and inconvenient locations: Alaska's oil deposits are mostly north of the Arctic Circle, and Canada's significant deposits of oil and natural gas are in the less severe but still challenging climates of northern Alberta.

It is tempting to exaggerate the impact of climate, resources, and the physical landscape as influences in the economic and political development of states and regions. As the experiences of Japan and Singapore (among others) attest, industrialization is possible without a significant resource base. Nonetheless, there can be little doubt that the physical environment has played a considerable role in the development of the United States and Canada.

Human Geography

Settlers arrived in North America from three different directions: northwest, east, and south. The region's first inhabitants arrived from northeastern Asia about 35,000 years ago over a land bridge that spanned what is today the Bering Sea and spread not only through North America but also through Middle and South America. In the large expanses of North America, they developed over 2,000 languages and a variety of lifestyles ranging from hunting and gathering to settled agriculture and the construction of cities. In 1492 indigenous peoples comprised the entirety of the North American population, and estimates of their total numbers vary widely from 1 million to 18 million. More than half a millennium later, indigenous peoples make up some 4 percent of Canada's population and less than 1 percent of the population of the United States: in other words, little more than 3 million in total. Their demise was brought about by the arrival of Europeans on the east coasts of the region and in much smaller numbers from Mexico to the south. Like the indigenous peoples of Australia and South America, indigenous North Americans had no resistance to many of the diseases that came from Europe, and their populations declined rapidly. Many of the survivors were displaced from their traditional lands to peripheral areas in the west and north of the region.

The Europeans who first colonized North America were primarily Spanish, Dutch, French, and British. British colonization and settlement ultimately dominated most of the region and is reflected today in the prevalence of the English language in both Canada and the United States. French colonial influence has been important in Canada, where French is today an official national language and the majority language in the province of Quebec. French influence also remains in parts of the United States acquired during the Louisiana Purchase, particularly in the state of Louisiana itself. Spanish culture and language initially arrived in North America from the south; large parts of the United States were Mexican territory before their acquisition by the United States in the mid-nineteenth century. This influence has been reinforced since that time with trade and immigration across the southern border of the United

States. In 2005, 14.5 percent of the U.S. population was classified as Hispanic or Latino by the U.S. census, a total of some 42 million people.

Another major group of settlers in North America arrived involuntarily as slaves from Africa. They settled mainly in the southeastern United States, where plantation agriculture was most prevalent. After emancipation African Americans spread to other parts of the country, primarily to urban areas. This migration increased in the twentieth century as the two world wars opened up jobs in the armaments industries. Today, blacks (most of them African Americans) make up some 12.5 percent of the population of the United States. Relatively few blacks migrated across the border; less than 2 percent of Canada's population is black.

In 2007 the combined population of the United States and Canada was 334 million people.⁴ Of these, 301 million lived in the United States, and 33.4 million lived in Canada. Both countries' populations continue to grow at a significantly higher rate than the populations of most other developed countries, although this is overwhelmingly as a result of immigration. In both the United States and Canada, native-born populations are growing slowly, whereas Japan and many European countries face declining populations in the twenty-first century. The spatial distribution of North America's population shows some clear patterns. First, large majorities in both the United States and Canada live in urban rather than rural areas. Second, most of the population lives along the west coast or in the eastern third of the continent. Third, over 75 percent of Canada's population lives along the country's southern fringe, within about 125 miles (200 kilometers) of the U.S. border. Fourth, the population center of North America continues to move to the west and south, as it has done for the past two centuries.

In many respects, the historical geography of the United States and Canada has a lot in common with that of Australia and New Zealand. All four countries were, prior to colonialism, occupied by indigenous peoples; in all but New Zealand large numbers of these first inhabitants died primarily as a result of diseases that arrived with Europeans. In all four countries, Britain became the colonial power and left a strong political, economic, and cultural legacy (the latter most evident in the predominance of the English language). In all four countries, large majorities are the descendants of European immigrants, although increasing numbers of recent migrants have come from Asia and, in the case of North America, Latin America. Mainly as a result of immigration, all four countries have increasing populations.

Middle America

Middle America contains eight countries (Mexico, Belize, Guatemala, Honduras, El Salvador, Nicaragua, Costa Rica, and Panama on the mainland and all of the countries in the Caribbean Sea) and in 2010 was home to 195 million people. The region is diverse in terms of its physical and human geographies, and geographers commonly try to make

sense of these differences by subdividing the region into two parts. Topography may appear to suggest a simple division between the Central American mainland and the islands, which circle from Mexico's Yucatan Peninsula to the eastern coastline of Venezuela. Closer examination, though, reveals that it makes more sense to conceive of the region as consisting of the low-lying, tropical, and largely coastal areas bordering the Caribbean (which some geographers have called the rimland) and the mountains, plateaus, and western coastal areas (called the mainland). This mainland-rimland distinction helps to explain not only the physical geographies of Middle America but also the distinctive historical and cultural geographies of the two parts of the region.

Middle America is funnel-shaped, its broad end at Mexico's northern border and the southern end of its stem at the border between Panama and Colombia. To the west is the eastern edge of the Pacific plate, part of the tectonically active Pacific Ring of Fire. Earthquakes and volcanic activity are common here, and the destruction they have caused in the region is an integral and ongoing part of Middle American history.

Tectonic activity is responsible for the mountain spine that runs the length of the Middle American isthmus and passes through all but one of the countries of the mainland. At the broad northern end of mainland Middle America, the mountain spine divides into two distinct ranges. The Sierra Madre Occidental and Sierra Madre Oriental are separated by a high interior plateau, most of it more than 5,000 feet above sea level. On the western and southern coasts of Middle America, a narrow coastal plain separates the Pacific Ocean from the highland interior; in some places there is no coastal plain at all, with sheer cliffs marking the coastline.

The physiography of the eastern coastline is very different from that of the west. Here, along the Caribbean, the coastal plain is much broader. Most of Belize lies less than 500 feet above sea level, as do most of Mexico's Yucatan Peninsula and the Caribbean coastlines of Guatemala, Honduras, Nicaragua, and Panama. Topographically, these regions have much more in common with the islands of the Caribbean than they do with the mainland areas to the west. These similarities extend beyond topography to climate and help explain why they are considered part of the rimland rather than the mainland.

The climates of Middle America are influenced by a variety of considerations, including latitude, topography, and westward-moving weather systems. Much of the region lies within the tropics, but the high elevations of the mainland moderate the effects of this tropical location, producing cooler and drier climates and protecting the interior from the full force of westward-moving storms (not uncommonly hurricanes). The Caribbean islands, in contrast, experience mainly tropical rain forest-type climates, and their easterly or windward sides (meaning the direction from which the wind blows) often bear the full brunt of storms. Recreational sailors appreciate these dependable winds; the islands rely heavily on tourism for economic development.

Climatic and topographic differences have played a crucial role in the history and development of Middle America. Indigenous societies of

the mainland and rimland were distinct, as were their colonial economies and societies and the cultural and political landscapes of the post-colonial era.

Human Geography

Middle America was home to several powerful and innovative civilizations whose ideas and influence spread throughout the region. The Olmec culture thrived from about 1200 BCE until about the end of the fourth century BCE. The Maya rose to preeminence in the region in the third century CE; the heartland of their empires was in the low-lying tropical lands of the Yucatan Peninsula and the highlands of the Mexican state of Chiapas, but they had a much wider territory of influence, which would have constituted a Maya region during that time period. This region was comprised of those who paid tribute to the Maya (a political relationship), those who shared a language or related languages (a linguistic relationship), and those with similar agricultural practices and religious beliefs (a cultural relationship). This Maya region might have survived the collapse of the Maya empire, since the linguistic and cultural commonalities would remain even after the political and economic ties fell away. Even today southern Mexico and northern Guatemala share a great deal in terms of the culture of those who live there. This cultural region exists but is also subsumed into larger regions of more recent origins.

A succession of other societies lived in the topographically and climatically different areas of Mexico's Central Valley. This was where the city of Teotihuacan was built, at its peak a city of as many as 100,000 people. The Aztec state arose in this upland area in the fourteenth century, centered on its capital of Tenochtitlan, a city largely destroyed by Hernandez Cortes and his army in 1521 and ultimately replaced with the Spanish colonial capital of Mexico City. As in much of the rest of the world, geographic circumstances and processes both impelled and facilitated the process of colonization in Middle America. Climate precluded the growing of peppers and other much-desired tropical spices in Europe, spurring trade with eastern and Southeast Asia (see Europe, Eastern Asia, and Southeast Asia sections for more information). European maritime exploration was driven in part by the search for economical and secure routes for the lucrative spice trade. And it was in part the search for a new route to the spice islands of Southeast Asia that led to the arrival of Columbus in Hispaniola in 1492.

The path of conquest of the Americas by Europeans was made easier by the historical geography of early human migrations and specifically by the lack of contact between the peoples of the Americas and those of Europe. In the tens of thousands of years since their ancestors' migratory paths diverged in Asia (see map of early human migrations), the people of Europe had been exposed to different climates, foodstuffs, and animals and, critically, different pathogens than their Western Hemisphere cousins. There are two theories about the one-way direction of disease (although there is some controversy about the origins and directionality of venereal diseases). One theory is that few animals

EARLY HUMAN MIGRATIONS

CARIBBEAN ISLANDS, CIRCA 100 BCE

were actually domesticated in the Americas; most of the deadly pandemics of history came from diseases passed to humans from domesticated animals. The other theory is that the early episodes of diseases such as measles, influenza, etc., killed the most vulnerable members of the European and Asian human populations; those who survived tended to have immunities that were often passed along to their offspring, gradually reducing these dangerous outbreaks to mere “children’s diseases.” Separated by tens of thousands of years of evolution and thousands of miles of ocean, the indigenous peoples of the Americas had developed a different set of immunities. When Europeans arrived in the Caribbean islands in Mexico, the diseases they carried with them had a devastating effect on local populations. European diseases rather than European weapons brought victory to the conquistadors. (Disease similarly devastated other indigenous populations, such as Australia’s Aborigines and the Khoisan peoples of southern Africa.) Epidemics disorganized once highly organized societies as communities suffered massive deaths, lost crops due to the loss of farm labor, and dispersed as people fled both the Spanish and their diseases. The pathogens often spread faster than the Spanish themselves, which meant that in many instances European descriptions of the “new” world were of a world on which they had already had immeasurable influence.

Colonization changed the human geographies of Middle America not only by annihilating local populations but also by bringing in outsiders along with their ideas, beliefs, and cultures. On the mainland, Spanish influence was strongest. The Spanish language gradually came to be the predominant tongue in most of the countries of the region, although indigenous languages were widely spoken by minorities; however, today speakers of indigenous languages comprise a majority only in Guatemala. Roman Catholicism, the religion of the colonists, is today the faith of the overwhelming majority of Middle Americans (albeit with modifications shaped by indigenous religions and cultures).

Several European powers vied for control of the rimland; their varied legacy is reflected in the modern cultural and political landscape of the area. Spain controlled the largest tracts of territory in the rimland, including Cuba, Puerto Rico, and the eastern part of Hispaniola (today the Dominican Republic). The British colonial holdings were also significant and included Jamaica, the Bahamas, Belize (formerly British Honduras), and the coastline of present-day Nicaragua. The largest French holding in the rimland was Haiti, where the majority of the population today speaks a language largely based on French. The Dutch and Danish also acquired Caribbean colonies, though their major colonial interests were elsewhere. The economic geographies of the mainland and rimland areas were quite distinctive during the colonial era, and the legacy of these differences remains today. The tropical rimland areas, particularly lower-lying and more accessible coastal areas, were particularly well suited to the production of plantation crops, most notably sugar. In some parts of the region, including Jamaica and Haiti, colonial powers brought slaves from Africa to provide the labor force for their plantations. The economic and cultural legacy of this period is evident today: majorities of the population of both Haiti and Jamaica are of African descent, and the economies of several of the countries in the Caribbean still rely on the export of tropical agricultural products as their main sources of revenue.

The end of the colonial era in most of Middle America came in the early nineteenth century, but this did not mean the end of powerful foreign influences in the region. As European domination waned, Middle America began to feel the consequences of its proximity to an increasingly powerful United States. The impact of the United States remains today throughout the region. In the case of Mexico, its very political boundaries are in part a legacy of U.S. influence and power. Economic geographies in the region reflect the interests of North American capital and markets (although simplistic, the notion of the “banana republic” encapsulated the idea of a Middle American economy whose economic and political landscape is dominated by a single tropical crop grown for export to the United States). The U.S. demand for labor has prompted the migration of millions of Middle Americans to the United States as well as to the labor-intensive factories established in Mexico and elsewhere to take advantage of local cheap labor and proximity to U.S. and global markets. All countries in the region have experienced U.S. efforts to influence the course of their domestic politics, frequently involving the use of direct or indirect military force.

South America

South America is understood as a region in large part because of its separateness as a landmass. It is surrounded by water except for a sliver of land connecting it to Central America. Thus, unlike the divisions of many Eurasian regions, the physical boundaries of this region generally make sense. Only the northern boundary, between Colombia and Panama, is obviously produced by politics rather than natural forces (Panama was part of Colombia until 1903). But it is not just physical characteristics that shape the region. The countries of South America (Argentina, Bolivia, Brazil, Chile, Colombia, Ecuador, French Guiana, Guyana, Paraguay, Peru, Suriname, Uruguay, and Venezuela) were almost all part of the colonial holdings of Spain or Portugal. (Guyana and Suriname began as Dutch colonies, with the British assuming control of Guyana in the early nineteenth century. French Guiana was colonized by the French in the seventeenth century.) The legacy of colonialism—arising from both colonizers' domination and indigenous resistance—shaped the economy, population, and aspects of the culture of the region. As centuries passed, European and native cultures acted upon each other as they developed. Of course, there are also notable differences in the areas colonized by different European powers. The region's population exceeded 370 million by 2005.

Physical Geography

The region of South America was separate from the other regions of the Western Hemisphere until 3 million years ago, when volcanic activity created the Panama Isthmus and connected the major landmasses. From this point animals were able to move from one region to another, and animals once found exclusively in South America, including armadillos and sloths, moved north. Other animals moved south, including llamas, which we now think of as quintessentially Andean animals. This exchange increased the range of plants and animals available for people to domesticate and use.

The region is defined by several quite distinct topographic and climatic features and subregions. The Andes mountains stretch from north to south along the western side of South America. Produced by tectonic activity, they are young and seismically active ranges. The Andes, with their high altitudes and challenges to agriculture and infrastructure development, have long shaped life in Argentina, Bolivia, Chile, Colombia, Ecuador, Peru, and Venezuela.

Apart from the mountains, South America also includes tropical areas, including the Amazon rain forest, and broad river basins, including that of the Amazon River, the largest river in the world by water volume. There are also deserts, especially the Atacama Desert in the southern reaches of the region, east of the Andes mountains, which gets remarkably little rainfall and is the driest desert on earth. The deserts, obviously, are scarcely populated. As is true in most regions, the coasts are most densely populated and the interior less so. However, in South America this pattern is more pronounced, with very high population

concentrations in urban metropolitan regions, which are generally on the coast or in the mountains and quite sparse populations in the rain forest and desert areas.

Human Geography

The earliest evidence of agriculture in South America is found in the Amazon Basin and dates to 6500 BCE, with evidence of animal domestication (the llama) and plant domestication (maize) in the Andes following this by 3,000 years, by 3200 BCE.⁴ The first signs of complex societies and empires occurred on the Peruvian coast, culminating in the emergence of the Chavin, a group with extensive trade relations along the coast that provided cultural influences for subsequent Andean empires, including the Inca. Before the rise of the Inca empire, smaller political units existed and extensive irrigation systems were built, but there was little urbanization and there were limited market systems, even though the highly varied topography of the area meant that there was considerable specialization in production. This fragmentation reflects the difficulty of uniting, economically or politically, highly mountainous terrain. Mountainous areas tend to have smaller farm plots, more dispersed populations, and greater cultural and linguistic diversity because they are harder to control. It is truly remarkable that the Inca empire was able to largely unite the Andes and the mountainous western coastal region in the early thirteenth century.

The Inca expanded existing infrastructure dramatically, building and maintaining 14,000 miles of road to connect the long, narrow, and dramatically mountainous territory that they controlled. Perhaps because of the importance of this infrastructure and transportation, they relied heavily on conscripted labor rather than taxing subjects in kind (collecting a percentage or fixed amount of agricultural production). Instead, men in the Inca empire served in the military and worked on public works projects for a certain amount of time each year. At some large-scale work projects drugs and alcohol were distributed to the workers to make them more content to be there. Each community under the Inca empire divided up its agricultural land, some set aside to feed locals, some dedicated to the empire and the gods. Under the Inca empire, the specialized production that resulted from the dramatic differences in climate and environment became the basis for extensive trade. At the height of the Inca empire, more food was produced throughout the Andes than is produced today.

The Inca empire stored surplus grain along its extensive road system to support troops and traders and in times of food shortages released it to communities in trouble. The Inca empire also attempted to quell conflict and dissatisfaction by bringing the children of conquered leaders to the capital, Cuzco, where they were raised to be loyal to the Inca and were later married to establish strategic alliances. When regions were seen as disloyal, some of the population would be moved to other parts of the empire to weaken challenges to Inca authority. However, like the Mexica (Aztec) empire, which apparently was experiencing some internal conflict, the Inca empire was in the midst of a struggle

for power between two brothers when the Spanish arrived. In addition to political conflict, smallpox had arrived—carried through indigenous contacts—before the Spaniards so that sections of the empire were already facing decreased populations and the consequent decrease in food production and social and political stability.

When the Spanish had control over most of the empire, they used the expressions of political power put in place by the Inca, including the mandatory labor system. Once the Spanish discovered the vast seams of silver in central Peru (now Bolivia) and the international demand for silver skyrocketed, conscripted labor was extended and used to mine the silver. This allowed the Spanish to make extraordinary profits but continued the process of demolishing the indigenous population. The global circulation of goods was not limited to silver. South American food products also diffused throughout the world. Potatoes, originally from the Andes, fed peasant communities from Ireland to Russia to China; corn, originally grown in Middle America but a staple throughout the Americas, was soon grown in Africa as a central part of colonial labor systems, since it requires relatively little effort per calorie and freed up African workers for forced labor in mines or plantations; manioc, native to Brazil, also became a staple in Africa. The diffusion of food supported the expansion of populations throughout the world.

On the Atlantic coast, the Portuguese found a different set of resources in Brazil. With no substantial stores of gold or silver, the Portuguese established plantation systems. By the 1530s, Brazilian sugar competed with sugar produced in the islands off the northwestern coast of Africa and, later, throughout the Atlantic and the Caribbean islands. These plantations were worked by slaves brought from Africa (some estimate that over a third of the slave trade was destined for Brazil), establishing the origins of a large Afro-Brazilian population that remains culturally significant today. On the eastern side of South America, population concentrates along the coasts even more than the western side, where there are vast capital cities at dramatically high altitudes. The Amazonian basin has long been populated by indigenous tribes but at relatively low densities and with the great cultural diversity that characterizes places with small dispersed populations. Some of these tribes were pulled into plantations as slave labor, many were defeated by disease, but some have remained independent for centuries. Today, the expansion of large-scale agriculture into the region leads to conflict with these populations.

Spreading Christianity was one of the justifications for the conquest of the Americas. Conquistadores were always accompanied by priests, some of whom had qualms about forced conversion, but many did not. While indigenous and African religions are still practiced and Protestant missionaries are increasingly successful in conversions, Catholicism has shaped the culture and politics of South America for all parts of the population. Catholicism has been simultaneously a tool for oppression and a voice for liberation and justice.

Following the American Revolution and the French Revolution, the Spanish colonies began to fight for independence, particularly after Napoleon Bonaparte invaded Spain. These local revolutions were generally

supported by propertied elites who were interested in liberating themselves from Spanish control but not in losing their power relative to the vast majority of the population, the indigenous population, or the Africans imported as slave labor. So, while there was a radical message in most independence movements throughout much of South America, independence led to the perpetuation of political and economic elites who were European rather than indigenous and who continued to exert power over the indigenous and black populations. Most countries continued the economic development begun under colonial rule, focusing on developing extractive economies and exporting primary products (metals extracted through mining or agricultural products). Much of the investment used to expand production came from Europe (especially Britain) and the United States. An American, Keith Minor, built railroads in Colombia and other countries in South America and Middle America; Americans and Europeans owned banana, coffee, and other plantations that exported food; and foreign companies provided financial and technological investment in mineral extraction throughout the region.

Overall, postindependence economic development produced more riches for the wealthy and growing poverty for the rest throughout South America and was the basis for increasing resistance from rural peasants and the urban poor and increasing repression from militarized governments. The proliferation of rebel groups (often Marxist) aroused U.S. concern, leading to U.S. interference and involvement in South American politics during the Cold War. During this period, the mountainous terrain of the Andean states of South America again proved difficult to control and dominate, as political and criminal threats to state control used the topography to hide from the military. Not surprisingly, many residents of the region found themselves caught between competing armed bands of men.

Today in the post-Cold War world when the United States is more focused on terrorism than the suppression of communist movements and many military governments have been displaced through democratic trends, a new set of leftist leaders has risen in South America. Venezuela, Brazil, and other countries have elected populist leaders, though all have faced internal resistance and international challenges. The near future will reveal if a new regional identity will emerge, one that articulates a new international economic agenda, a new role for indigenous and African peoples, and a new political vision.

Oceania

Nowhere is the problematic nature of regions clearer than in the case of the region encompassing Australia, New Zealand, and the South Pacific, a region frequently called Oceania. Indeed, even calling this area a region stretches the notion of region to its limits. In terms of sheer area, it is the largest of the regions we identify here. It extends longitudinally from western Australia (about the same longitude as Hong Kong) to Pitcairn Islands (the easternmost of which is about the same longitude as Vancouver). The northern Mariana Islands lie as far as 20° N, and New

Zealand's South Island reaches some 46° S. Although immense in extent, land areas make up only a small portion of the area, totaling an area roughly equal to that of the contiguous states of the United States. The region's population is tiny; only 34 million people, or just over 0.5 percent of the total global population, live here. This population is very unevenly distributed: the three largest and most populous countries in the region—Australia, New Zealand, and Papua New Guinea—are home to some 95 percent of the region's population. One in 8 people in the region live in a single metropolitan area, Sydney. The smallest countries are miniscule: the Republic of Tuvalu has only 11,800 inhabitants and consists of nine coral atolls with a combined area of 10 square miles (26 square kilometers), one-tenth the size of the District of Columbia.

The region is also extremely diverse in terms of most aspects of its physical landscapes and human populations. In this very diversity, however, lies the common geographic denominator that makes it possible to define the South Pacific as a region. All of the lands of the region are remote, largely isolated not only from other population centers on earth but frequently also from one another. Australian historian Geoffrey Blainey has argued that his own country's history has been shaped by the "tyranny of distance."⁵ The same argument might equally apply to the rest of the region.

For much of the region, remoteness is a consequence of insularity. Tonga and Nauru, for example, are isolated because they are small and remote islands. Much of Papua New Guinea, however, is isolated not as much by the island's distance from its neighbors (which is not very great) but rather by the ruggedness of its terrain and the density of its vegetation, which combine to make travel and transportation very difficult. For Australia, the tyranny of distance lies not only in distances to other continents but also in the distance between its major population centers, which requires surmounting the continent's own size and forbidding climates. The influence of distance is apparent in the early settlement of the South Pacific as well as in its colonial past. It helps account for the vast diversity of cultures and languages in the region as well as the obstacles faced by the modern economies of the region as they attempt to compete in global markets. Long before humans arrived in this region, distance and isolation had allowed the process of evolution to produce a range of unusual ecosystems in the region. Nowhere in the world are there as many marsupial species as there are in Australia and New Guinea. And in few places that humans settled did they find, as they did in New Zealand, ecosystems dominated by birds and devoid of all terrestrial mammals.

If the continent of Antarctica is to be considered part of any world region (a debatable issue on the basis of remoteness), it makes sense to include the continent here. From the perspective of human geography, Antarctica does not really fall within any world region since it has no permanent human population, no states, and, aside from the fishing areas around it, no economic activity. Its role in world history has thus far been negligible. From the perspective of the biologist or physical geography, however, it is a substantial landmass twice the size of Australia and every bit as intriguing as any other part of the world.

The vast region of Oceania can be divided into four subregions: Australia and New Zealand, the economic giants of the region and two of the three largest countries; Melanesia, the part of the Western Pacific that includes the islands of New Guinea, the Solomon Islands, Fiji, Vanuatu, and New Caledonia; Micronesia, the small islands on or north of the equator; and Polynesia, which includes the eastern Pacific Islands. This is somewhat complicated by the inclusion of the state of Hawaii, with its remote location, distinctive geology, and Polynesian cultural heritage but political inclusion in the United States of America. By and large, however, the 50th state should be considered a part of Oceania despite its political status.

Physical Geography

The largest landmass in the Pacific region, the continent of Australia, lies atop the Australian plate, and it is one of the oldest and most stable parts of the earth's crust. Earthquakes are rare, and the most recent volcanic activity took place more than 5,000 years ago. Its great age means that the continent has long been exposed to erosion, and the western region consists largely of low relief areas (those showing little differentiation in elevation) aside from the Great Dividing Range (near the east coast) and some smaller ranges in the interior.

By contrast, most the rest of the land area of the region owes its existence to tectonic activity that has taken place in the recent geological past. The plate boundaries that comprise the Pacific Ring of Fire pass beneath New Zealand, the island of New Guinea, and the western parts of Micronesia. The Southern Alps of New Zealand's South Island, which rise to over 12,000 feet above sea level, are the product of mountain building along a plate boundary; so too are the volcanoes and geothermal springs of the country's North Island. Another plate boundary had produced the rugged terrain of the island of New Guinea: Papua New Guinea's highest peak is nearly 15,000 feet high. Ocean floor volcanoes, either along plate boundaries or geological hot spots, are in some places high enough to protrude above the ocean surface, creating many of the smaller islands of the Pacific (including some of the islands of Fiji, American Samoa, Tonga, and Hawaii).

Some of the older volcanic islands have been eroded away over time, leaving behind the coral reefs that grew along their fringes. These are the low-lying atolls that make up such islands as those of Kiribati and Tuvalu. Their low elevations (some rise to less than 6.5 feet [2 meters] above sea level) make them particularly vulnerable to future sea-level rises that might accompany global climate change.

As a result of its large latitudinal extent and its extremes of relief, the climates of the South Pacific region are varied (see climate map). Although much of the region lies within the tropics and has tropical climates, in many places climates are affected by altitude. Papua New Guinea lies very close to the equator, and although tropical rain forest climates dominate its lower-lying areas, the country's highest peaks receive regular snowfall and even have small glaciers. In contrast, Austra-

lia is the driest of all the world's inhabited continents. Parts of New Zealand, by contrast, are among the wettest.

Human Geography

Location has played a pivotal role in the history of the South Pacific region from the time of earliest human settlement until the present. Those parts of the region closest to the Eurasian landmass were among the first areas to be settled by early humans after their departure from Africa. The remoter parts of the region were some of the most recently settled. Oceania was not high on the list of European colonial priorities and was for the most part colonized in the nineteenth century.

The first human settlers arrived on the island of New Guinea some 46,000–50,000 years ago when sea levels were below their current levels and a land bridge linked many of the now island parts of Southeast Asia. The same wave of migration brought the first human settlers to the Australian mainland and to Tasmania, at that time linked to the rest of the continent. The descendants of these early settlers, Australian Aborigines and the indigenous peoples of New Guinea, are some of today's longest-surviving cultures.

In contrast, most of the remaining islands of the South Pacific were among the last of the earth's habitable landmasses to be settled. New Zealand, which is only 932 miles (1,500 kilometers) from Australia, was not settled until some 45,000 years later. Whereas Australia's first settlers probably came by land bridges from the Asian mainland during cold, dry periods when sea levels fell, New Zealand was peopled by seafarers from the Polynesian islands. Human settlement of these islands, in turn, was impossible until the development of the technology of transportation and science of navigation made travel possible.

The physical fragmentation of the lands of the South Pacific is reflected in the region's cultural geography. Despite its small population, the South Pacific region accounts for 19 percent of all of the languages in the world.⁶ Of these, a remarkable 820 are found in Papua New Guinea alone, a consequence of the difficulties of travel and communication within that mountainous and densely vegetated country. Prior to the arrival of Europeans, indigenous Australians spoke over 300 languages, in part a reflection of the size and difficulties of travel within this largely arid continent.

The countries of Oceania are farther from Europe than any other places on earth, and so it is not surprising that they were low on the list of colonial priorities. Indeed, the first British penal settlements on Australia owed their existence in part to the continent's remoteness. Australia itself was the prison, escape made virtually impossible by deserts, distance, and oceans. When colonialism did arrive, though, it profoundly reshaped the region's cultural geographies. Australia is today a multi-cultural continent as it was in precolonial times, but the predominant cultural influences today are European and, increasingly, Asian. More Australians trace their origins to the United Kingdom than anywhere else, a legacy of colonial settlement and the "White Australia" policies

that favored European immigration for most of the postcolonial era. Likewise, New Zealand's population is dominated by people of British extraction, and the dominant language is English.

Indigenous peoples today comprise only a minority of the populations of both Australia and New Zealand. The isolation of the region was in part to blame for this: Australia's Aboriginal peoples had been protected from the diseases of the outside world by 40,000–60,000 years on their remote island location. When Europeans arrived, bringing new diseases with them, indigenous peoples quickly fell prey to infections against which they had no immunity. Laid waste by disease and vastly outnumbered by new arrivals, Aboriginals today make up less than 2 percent of Australia's population. The fate of New Zealand's first peoples, the Maori, was rather different. A much more homogenous population than Australian Aborigines, they arrived in the islands about a millennium before European colonization. They proved to be more resistant to European diseases than Australian Aborigines and mounted a fierce resistance to European conquest. The forces of colonialism ultimately prevailed, but today Maori make up nearly 15 percent of the country's population, and the Maori language is one of the country's two official languages.

Like Australia and New Zealand, the French territory of New Caledonia has a significant population of European descent. They number about a third of the territory's population, but the majority of the population are of Melanesian and other Pacific extraction. One other country in the region has a population geography profoundly affected by colonialism. During the colonial era, Indian indentured workers were recruited to work on plantations in the British colony of Fiji. Today, Indo-Fijians make up about half of the country's population, with indigenous Fijians comprising most of the remainder. This cultural geography is reflected in the country's political and economic landscape.

Distance and isolation have long shaped the history of Oceania. So too have technologies that mitigated the effects of distance. New technologies of boatbuilding made it possible for the first humans to reach the remote South Pacific islands. Sailing ships facilitated the colonization of the region by Europeans. Steamships and refrigeration allowed Australia and New Zealand to export meat and other agricultural produce to distant markets, and long-range aircraft allowed many of the countries in the region to promote themselves as tourist destinations. The Internet gave Tonga and Tuvalu the opportunity to supplement their meager foreign exchange revenues by selling Internet domain names (with the suffixes .to and .tv) and allowed Nauru to establish itself as an offshore banking location (briefly, at least, until money laundering charges put an end to this venture). In short, although distance has influenced the history of Australia, New Zealand, and the South Pacific, its influence has constantly changed and will continue to do so in the future.

Conclusion

As we have seen, regions are shaped by physical geography but are fundamentally created by humans. Regions are ideas and thus are funda-

mentally social products, held together by social and cultural cohesion. They are also historically constructed in the sense that the cultures that provide them with definition change over time. To understand the significance of regional geography and world history, we must recognize the interactions among environmental, social, and historical features. For example, while sub-Saharan Africa is bounded by the barriers of ocean and desert, the significance of those barriers has changed with time due to environmental, social, and technological changes. Oceania, on the other hand, gets its character (and name) from the seas and is unified by great expanses of water, but that coherence and the region's isolation from the rest of the world continue to change as distance itself seems less significant. As with the North African and western Asian cultural region of Dar al Islam or medieval European Christendom, some regions are unified by a common belief and other cultural ties. But these cultural ties are not timeless or ahistorical; they have emerged and grown and evolved over time and will continue to do so. As cultures adapt to new circumstances, so will the regions that they currently define. Borders might shift, as will defining characteristics. Environmental developments also have an impact on the regions that we use to understand the world. In conclusion, while regions are a necessary conceptual tool for ordering our thinking about the world and world history, they should not be imagined as a static tool.

Humans migrated into every area of earth from their African origins and have established permanent settlements everywhere except Antarctica. People developed tools and technologies that allowed them to survive in the most marginal areas, from deserts to frozen tundras. Populations—driven by war, persecution, or in search of economic opportunity—continue to shift and relocate. In the essay below, Dr. Manning considers the history of migration, a fascinating journey.

—Carolyn Neel

Migration in Human History

Patrick Manning

The common pattern of human migration is for a minority of young adults to leave home and move away to a destination where the landscape and culture are different. Some migrants move to sparsely settled frontiers, while others move to centers of population; some return home, while others remain at their destination or even move farther. Migrations are initiated by human decision but also by natural disasters that can force whole communities to move. The motivations of migrants include adventure, escape, expulsion, commerce, war, and a search for resources to bring back to their home community.

Biological comparisons show that while various species have evolved quite different migration patterns, there remain some underlying similarities. Migration is the movement of individuals or populations from one habitat to another for reasons that serve a function in the life cycle of the individual and the species. Thus, *Homo erectus* spread, beginning a million years ago, from eastern Africa to much of the Old World and gave rise to successor species in Asia, Europe, and Africa.

While *Homo sapiens* first emerged on the east African savannas some 200,000 years ago, it is now speculated that not until 70,000–90,000 years ago did our ancestors gain improved vocal articulation and with it the beginnings of fully articulated speech. With the rise of language, human communities gained distinctive identities because of the gradual separation of their language and customs. Those who migrated from one community to another had to learn new languages and customs. This pattern emphasized learning in individuals, the exchange of customs and technologies among groups, and innovations in assembling old ideas and new. Consequently, migration facilitated an acceleration of social evolution that began to account for most of the change in human societies. Such cross-community migration remains the basic style of human migration. The same underlying logic of crossing community boundaries and generating social innovations continues to this day but has transformed human society almost beyond recognition.

The ancestral African habitat of *Homo sapiens* centered on tropical savannas, including locations at water's edge. Humans hunted and gathered but also ate plants and animals from the waters and learned to swim and to create watercraft. These elements—the ancient migratory

practices of mammals, the new practice of cross-community migration, and the reliance of humans on movement across water—provided a basis for modern *Homo sapiens* to occupy all the territories of the earth.

From 70,000 BP to 10,000 BP

In the early human migrations, the principal movements were to territories ecologically similar to those of the east African homeland, first within tropical Africa and then in Asia. Humans left Africa not, as is commonly asserted, by moving north to the Sinai and the Mediterranean but instead by moving along the Indian Ocean coast. With early watercraft our ancestors were able to cross the 6.2 miles (10 kilometers) from Somalia to southern Arabia and remain within a relatively constant environment. (Sea levels were then much lower than now.) In the time between 70,000 years ago and 50,000 years ago, human populations worked their way along the Indian Ocean coastline, presumably on both land and sea, to the east of what is now Indonesia. Australia and New Guinea—then joined in the continent of Sahul—lay across a great oceanic strait, but the migrants crossed open water exceeding 60 miles wide (100 kilometers) and did so on multiple occasions, as the genetic record attests. Similarly, humans followed the coast of the South China Sea, eventually reaching more northerly and even-temperate zones.

Human migrants, having mastered the tropics, did not automatically move north to temperate zones, since the colder climate and the sharply different flora and fauna required new technology. From well-dated European remains, we know that *Homo sapiens* (known locally as Cro-

Magnon) reached Europe as early as 40,000 years ago. What is not known is the route by which they arrived. Four major routes were available for entry to the temperate zone from the tropics: the Nile-Fertile Crescent corridor, the Persian Gulf-Caucasus corridor, the corridor of the Southeast Asian river valleys, and the Pacific coast of China. Along one or more of these routes, humans learned to live with the sharply

varying temperatures and rapidly running rivers of the temperate zone. With this achievement, they gained the ability to range all across the Eurasian grasslands along routes that have been used ever since.

With each human colonization of a new continent, a great die-off of megafauna soon followed: this was the case first in Australia, then in temperate Eurasia, and later in the Americas. This was destructive behavior at one level but also showed the potential of human migration for bringing about change. Human migrants, in entering new ecologies, thus transformed them as well as accommodating to them, making each into a new habitat. While most other species were limited to a single habitat, the notion of “habitat” must be redefined for humans: a human habitat is not only a natural ecology but also a set of customs for life within that ecology. The social function of cross-community migration

was to create and spread innovations from habitat to habitat, so that migrations have been a significantly adaptive behavior.

At each stage in human history, most people remained in the land of their birth, yet migrants were sufficient in number to settle new areas. Those who stayed put in a given region underwent steady pressures of natural selection. Such adaptive pressures gradually brought about differences in superficial characteristics, such as skin color, hair type, and body size and shape. We can say, therefore, that the physical differences we label as “race” exist because of migration and that they mostly emerged between 40,000 and 10,000 years ago.

As early as 30,000 years ago, migrants succeeded in moving farther north and east, into North America. Both land and sea migrations to North America are known to have taken place in later times, so either mode of transportation could have worked for the first entry. Travel by sea may have been more feasible in this cool and ice-ridden era: the Pacific kelp beds provided offshore nourishment in a great arc along the coast from the South China Sea to South America.

Once in the Americas, humans migrated steadily to occupy the hemisphere. This process, though not yet known in detail, is likely to reveal much of the cross-community patterns of early human migration. Migrants moved from Arctic lands to temperate forests to grasslands to desert regions to tropical forests and on to further ecologies, though the Pacific coastline provided a substantial continuity in ecology that made movement relatively easy. Adaptation to each new ecology was a challenge. Here again, the experience of different communities, separated by language and culture, enabled them to develop their own adaptations; the process of migration spread the innovations of each group to others, and the interchange of ideas led to still more innovations. Thus, the Clovis culture, with its focus on finely honed arrowheads, was long thought to represent the first arrival of humans in North America. It is now understood to reflect the spread, among populations already in place, of an innovation in arrow technology that found wide use.

From 10,000 BP to 5,000 BP

The domestication of plants and animals, along with other technological advances, brought new patterns of migratory movement on foot, in association with animals, and by water. Studies of agriculture have gradually shown that food production, supplementing food gathering, was not a unique invention but instead was a repeated inspiration provoked by similar situations. A worldwide climate change provoked the development of agriculture in several privileged regions. Those regions shared physical relief and botanical variety, so that numerous plants could be experimented with. After the low-temperature trough of the Ice Age 18,000 years ago, temperatures began to rise: vegetation flourished, and humans began to depend on gathering expanding food supplies. But a thousand-year cold snap some 11,000 years ago (known as the Younger Dryas) brought a severe decline in food supplies and an impetus to discover ways to produce rather than just gather food. Responses

to this crisis brought the production of wheat in the Fertile Crescent, taro in New Guinea, rice in Southeast Asia, millet in Ethiopia, squash in South America, and sorghum in the Sahara. Populations grew with the development of agriculture; in addition, these and neighboring populations experimented with the domestication of animals and the creation of new implements, especially pottery.

Agriculture brought higher population density, development of new diseases, and migration of both humans and disease vectors. Jared Diamond and Peter Bellwood have argued that the agricultural populations expanded systematically in number and in territory in contrast to their neighbors. Another possibility, however, is that the techniques of agriculture spread more rapidly than the initial farming populations. Did the farming peoples spread, or did the ideas of farming spread? Was it demic migration (in which a single community expands) or cross-community migration (in which people and ideas moved through networks)? While the full results are not yet in, the evidence is just as strong for a patchwork of cases. Rice may have spread through Southeast Asia in the expansion of farming community, while wheat may have expanded through western Asia through its adoption by different communities.

From 5,000 BP to 2,500 BP

The domestication of horses in western central Asia some five thousand years ago brought an extraordinary expansion in mobility for those who controlled these animals. Harnessed to two-wheeled chariots, horses enabled peoples of the Caspian Sea region to raid and conquer in all directions. Surrounding states, at first suffering conquest, learned the new technology and later expanded their realms. Later, as saddles were

developed, the cavalry became an even more formidable tool of war. The military use of horses was sufficient to remake the political map of Eurasia from end to end, bringing migration both by conquerors and conquered.

In this era, thanks to evidence not only from language but also from archaeology and written texts, we can document some of the greater complexities in migration. An outstanding example is that of the

Lapita culture of the Bismarck Archipelago. There, the feedback and interaction of Austronesian migrants from the west with Indo-Pacific-speaking inhabitants of New Guinea and surrounding islands resulted in a synthesis of cultural and technical processes. Out of this cross-cultural exchange emerged the Polynesians, with a technology and social order enabling them to sail into the far reaches of the Pacific, colonizing the remaining islands.

Forced migration—the expulsion of people by human or natural causes—led migrants into catastrophic departure from their homes,

Harnessed to two-wheeled chariots, horses enabled peoples of the Caspian Sea region to raid and conquer in all directions.

Surrounding states, at first suffering conquest, learned the new technology and later expanded their realms.

movement through unfamiliar regions, and settlement in other lands. Such migrations, which have existed for all human time, became well documented in this era. Enslavement, an outstanding form of forced migration, expanded in this era, especially at the fringes of states from the Mediterranean through Iran.

Early stages of urbanization in this era provide a reminder that migrants gravitated toward centers of population density as much as toward sparse frontiers. In this era the cities and dense agricultural populations of Egypt, Mesopotamia, the valleys of the Indus River and the Yellow River, the Peruvian coast, and the Valley of Mexico emerged as major centers of population.

More striking than the growth of early cities in this era were the large-scale migrations and social transformations of large regions in this era, as documented through study of language and archaeology. The Austronesian-speaking migrants, who occupied most of the habitable areas of the Pacific and much of Southeast Asia within the past five thousand years, were discussed earlier. In the same period, Indo-European speakers expanded from a homeland in the region of the Black Sea and spread both east and west, becoming dominant in virtually all of Europe and as far south and east as northern India. Also in the same period, Bantu-speaking migrants set out from a homeland in southeastern Nigeria and expanded repeatedly south and east, ultimately remaking the language and perhaps the population of all central and southern Africa. They occupied a territory as large as that of the Indo-European speakers, and they too began as farmers.

Other groups, smaller in number but still of historical importance, included the Na-Dene speakers, who moved from central Asia to the Canadian region of Athabasca, some of whom later moved south to become the Navajo. Migrants from northern California to the south of Mexico, with migration completed some 3,000 years ago, became the Maya; in Australia the Pama-Nyungan spread out to dominate much of the continent. Phoenicians, Greeks, and Romans expanded to settle much of the Mediterranean and Black Sea basins.

From 500 BCE to 1200 CE

New patterns of migration emerged in this period centered especially in the densest part of the world's population, along the Eurasian and African river valleys and by the shores of the Mediterranean and the Indian Ocean. An accumulation of social innovation brought new patterns in innovation. Formal commerce, great empires, and large-scale organized religions each brought new patterns of migration.

The continuing development of military technology—and especially advances in the use of horses—brought the occasional absorption of regional monarchies into huge empires. From the first large-scale empire, that of Persia, to those that followed it in rapid succession—the Hellenistic, Roman, Qin, Han, and Mauryan—the powers of monarchies and bureaucracies now dispatched armies and navies in distant campaigns, brought artists and craftsmen to their capitals, and encouraged travel

Caravan crossing the Silk Road. Detail of the map of Asia, from the Catalan Atlas, Spain, Majorca, fourteenth century CE. (Bildarchiv Preussischer Kulturbesitz/Art Resource, NY)

within their domains. The succeeding empires of the Gupta, the Umayyads, Abbasids, Tang, and Song similarly stimulated migration.

Empires were not alone as causes of migration. Documents from this era show how migrations of small numbers of people, especially merchants and religious missionaries, could bring major social transformations. The expansion of formal trade in the first millennium BCE—with the development of money, the beginnings of banking, construction of ports and caravanserais—enabled merchant families to travel and sustain long-distance connections necessary to the movement of commodities. Similarly, the formation at much the same time of large-scale religions—Zoroastrian, Judaic, Buddhist, Christian, Hindu, Muslim, and others—brought migrations and connections among the faithful. Networks of family, faith, and commercial interest sustained the movement and connection of migrants over large areas. The significance of return migration is also evident in documents on merchant and missionary migrants. Religion, in particular, may have expanded more through the preaching of individual missionaries than through the invasion and conquest of armies.

The rise of empire and commerce also provided scope for the expansion of enslavement. For those captured, whether in war or by kidnapping, their movement and sale required a network of a different sort, including those who guarded them, fed them, and transported them to their destination.

Migrations of types well documented in earlier times continued in this era. Urbanization brought such cities as Alexandria, Rome, Constantinople, Baghdad, and the Chinese capitals. Turkish and Arab migrants, accompanied by their herds of goats, cattle, camels, and horses, moved into both agricultural and pastoral regions. The Vikings, among the

most spectacular of migrants, conquered, traded, and settled for some 300 years before the impulse subsided.

From 1200 CE to 1850 CE

The Mongol conquests of the thirteenth century extended the logistics of communication and control all across Eurasia, including major naval expeditions along the Pacific coast. In the thirteenth and fourteenth centuries, Mongol rule ensured intense cultural interaction among eastern, central, and western Asia. Mongol successors, notably Timur, sustained both the furious warfare and the intervening periods of peace and commerce in central and western Asia to the sixteenth century.

As routes across the lands of the Old World widened, maritime technology advanced in all the oceans. An early Chinese lead in long-distance voyaging could not be sustained, so it was European voyagers who achieved decisive advances in technology and social organization through long-distance seafaring. These voyages linked more tightly the seas of the Old World, drew western Africa more tightly into the Old World, and opened the Atlantic and the Pacific to navigation and migration.

In the eras of both Mongol and European dominance of long-distance routes, forced migration reached its peak as a process of long-distance human movements. Under the Mongols, war displaced populations from China to Hungary. Enslavement became central to war and politics, as Turkish, east African, and Caucasian slave-soldiers became central to the regimes of the great powers. Overlaying this terrestrial wave of enslavement was a steadily expanding maritime slave trade. While 2 million Europeans migrated to the Americas from the voyage of Columbus to 1850, over 10 million enslaved Africans made the voyage to the Americas in the same era.

The global reach of empires on land and sea brought about the interconnection investment and seizure of resources—primitive accumulation, in the words of Karl Marx—that made possible dramatic global economic and demographic growth in the nineteenth century. New cities grew along new commercial routes; at the end of this era, European and American cities grew at the expense of others.

Enslavement became central to war and politics, as Turkish, east African, and Caucasian slave-soldiers became central to the regimes of the great powers. Overlaying this terrestrial wave of enslavement was a steadily expanding maritime slave trade.

From 1850 CE to the Present

Rather suddenly in the middle of the nineteenth century, the principal character of long-distance migration shifted from the forced migration of captives bound for slavery to voluntary migration (though many of these migrants were semivoluntary contract laborers). Sometimes it took a crisis to launch the flow of migrants, as with the potato famine of 1845–1849 in Ireland. The outstanding change, however, was the

development of new technology, especially steamships that traveled dependably and cheaply but also telegraphs to convey information on conditions worldwide and the rise of industrial production and expanded demand for minerals and agricultural produce. Whereas 10 million Africans crossed the Atlantic as slaves from 1650 to 1850, nearly 50 million Europeans crossed the Atlantic from 1840 to 1940, and another 80 million migrants moved from India and China.

Two regions of sparse population—North and South America and Southeast Asia—each absorbed over 30 million immigrants. Some became industrial workers, others agricultural workers, still others miners, and many entered service industries.

In this era of expanded migration, the networks of voluntary migration became clear. Advertisements from the lands of settlement circulated in lands of departure, shipping companies competed for passengers, and small-scale labor recruiters gathered their collections of prospective workers and often accompanied them to their destinations.

With the great expansion in migrant flows, communities, states, and business firms sought ways of regulating and sometimes restricting migrants. In North America, where immigrant European and Chinese workers competed for work, those of European ancestry were able to campaign successfully for restrictions on Chinese migration. More generally, in the late-nineteenth-century era of growing national identities and more centralized national states, borders began to be constructed as ways of keeping migrants out. Where migrants had previously been restricted mostly by the cost of travel, they were now restricted in addition by quarantine for possible disease and by distinctions separating legal and illegal migrants. At the extreme, genocidal killings took place: heightened views of national identity sometimes led to decisions to homogenize the nation by expelling and even executing those ethnic or political groups identified as dangerous to the nation.

In much of the period after 1850, it appeared that migration was mainly from crowded regions to sparsely populated regions. With time, however, the dominant pattern turned out to be the opposite. Urbanization—the movement of people from rural areas or small towns to centers of population—expanded as never before. In the last half of the twentieth century, a dozen urban areas grew to include 20 million inhabitants or more. The urban settlers, in addition, came primarily from the immediate hinterland of the cities rather than from great distances. As a result, human society reached a tipping point at the beginning of the twenty-first century in which a majority of the human population came to live in urban rather than rural areas.

Migration remains a mix of old and new. With the expansion of higher education, one of the new migratory trends is that in which students leave their home and even their country to attend university and prepare for their role in a high-tech world. Yet this same process includes much that is habitual for humans. That is, young adults leave home, travel a distance, cross social boundaries, and learn new languages and customs (now those of the academic world); some of them will return home after the experience, while others will migrate farther. The ancient human pattern of cross-community migration has now been put

in the service of contemporary globalization, demonstrating the role of underlying human habits in even the most dramatic of changes.

Most animals have the ability to communicate, to one degree or another, but none to the extent of humans. One of the hallmarks of humankind is the ability to communicate complex symbolic ideas. We are able to convey to each other and to our successors not only instructions but a complex world-view. Human adaptation to diverse conditions—environmental, political, theological, etc.—depends on our ability to communicate with each other. Below, Dr. Haarmann quite eloquently discusses the role of language in human development.

—Carolyn Neel

Language Evolution and the History of Languages

Harald Haarmann

By the time humans became tool makers, they were communicating cultural concepts by means of signs and symbols. This capacity for symbolic activity was a precondition for the development of language.

Language is an expressive vehicle used by humans to craft identities, to create cultural environments, to channel intentionality, to give profile to various worldviews, to express feelings and emotions, and to make sense of the world. For more than 200 years, the structures of languages and the sets of rules specific to each individual linguistic system have been the object of intensive linguistic analysis.

When did language develop as an operational system? Who were the first humans to use speech? Is language limited to our species (*Homo sapiens sapiens*), or were archaic humans, such as Neanderthal, also able to speak? Did language emerge as a fully developed technology, or did it evolve in stages?

Although long neglected, the study of language evolution has become a preferred field of study among linguists, anthropologists, and paleontologists. In particular, the evolutionary transition in communicational skills from the Neanderthal stage to that of modern humans has been investigated with great scrutiny. There are two basic approaches to understanding the development of linguistic structures during this transitional phase. One is based on the assumption that human linguistic ability matured in an evolutionary leap, while the complex languages spoken by modern humans developed from a protolanguage with simple, if not simplistic, structures.¹ The other approach advocates a gradual evolution of linguistic structures resulting from “the co-evolution of language and the human brain.”²

The idea of the existence of a protolanguage emerged out of the study of pidgin and creole languages. In the processes of pidginization and creolization, an indigenous language fuses with a colonial language, and the structures of the involved languages usually become simplified to form a new set of phonetic sounds, new grammatical and syntactic rules, and a reduced vocabulary. Since the 1970s, the study of such processes has produced many insights into how languages function with

simplified linguistic structures. Such insights have inspired some scholars to assume the emergence of a protolanguage used by early hominid species such as Neanderthal and *Homo erectus*.³

A certain capacity for using language may have been present in early humans, although its full-fledged evolution as complex language is related exclusively to *Homo sapiens sapiens*.⁴ There is anatomical evidence for the capacity to use language in Neanderthals, a hyoid bone that “lies between the root of the tongue and the larynx, and is connected to the muscles of the jaw, larynx, and tongue.”⁵ The hyoid bone in the Neanderthal skeleton is quite similar to that of modern humans.

Although the findings from creolistic studies can be helpful for understanding the construction of simple languages, there are still quandaries in terms of perceiving the progress of complex linguistic development. While the structures of most pidgin and creole languages are much simpler than the structures of those languages that fused to create them, creole languages are still much more complex than the communication skills assumed for earlier hominid species. The construct of a protolanguage spoken by hominids still lacks the potential to explain the transition to the stage of complex language.

The concept of a gradual evolution of the human brain along with the sequential appearance of more complex language structures shifts the idea of an evolutionary leap into a series of developmental steps. In some attempts by linguists to grade evolutionary levels, individual steps have been perceived as the independent developments of linguistic structures, as if phonetics, grammar, syntax, and lexicon were separated from each other.⁶ What is sometimes missed in an examination of internal linguistic changes is the intricate synchronicity of developments.

In all pertinent approaches to a gradation of the evolutionary process toward complex language, individual steps have been reconstructed by observing language acquisition in children.⁷ It is generally agreed among

linguists that as a child develops language skills, processes are repeated during individual socialization that originally took many thousands of years to evolve in different hominid species.

By recognizing the dynamics of a synchronic evolution of phonetic, grammatical, syntactical, and lexical structures, the following developmental steps—from rudimentary

means of communication to the sophisticated stage of complex language—can be described.⁸ This process lasted longer than 1.5 million years, covering the presence of three hominid species: *Homo erectus*, Neanderthal, and modern humans.

In all pertinent approaches to a gradation of the evolutionary process toward complex language, individual steps have been reconstructed by observing language acquisition in children.

Communicating with Signals and Interjections

Early humans, experimenting with sounds produced by the vocal cords, began to associate specific sounds or sound groups with communica-

tional meanings. Elements of sound use, similar to those used in this early stage, are still functioning in complex modern languages (e.g., “shh!” for giving the signal “be quiet!”; “hi” as a greeting; or “wow!” for expressing astonishment). The amount of individual signals may have been small in the repertory of *Homo erectus* and other hominids, but the inventory of signals and their purposes gradually increased.

Wording the Environment

A precondition for this step is the capacity to distinguish between individual objects and to assign to them different sounds with representational meaning. It is uncertain precisely how the representational dimension of cognition relates to verbal utterances.

The simplest process of wording the environment is the deliberate imitation of acoustic and visual effects typical of specific animals as well as the sounds and noises produced by natural forces such as the wind, the waves of the sea, water running in a brook, the noise of thunder, the sound of a burning fire, and other phenomena.

It has to be emphasized that archaic humans, for whom this stage of protolanguage may be postulated, had a rather limited capability for producing speech sounds. In all probability, early *Homo sapiens* could only produce two vowel qualities (like e and a) and perhaps eight consonants (p, b, t, d, s, h, m, n), although they were anatomically capable of producing a glottal stop, a sound that is still present in languages such as German, Danish, and Finnish.

This second stage of language evolution is still visible in the use of onomatopoeic (sound-imitating) expressions that exist in every historical and recent language. The amount of onomatopoeic elements in the lexicon of complex languages varies considerably. Finnish and Japanese, for instance, have a high proportion of onomatopoeic elements. In complex languages, onomatopoeic expressions are embedded in the phonetic, grammatical, and lexical system like other words. Nevertheless, their structures may differ from other words in certain properties. For example, in Lithuanian, “most onomatopoeic words are monosyllabic (they may comprise only consonants).”⁹

Talking about Things

Talking about things requires more than the ability to represent objects by linguistic signs. It requires the capacity to reflect about things, to identify interrelations between objects and living beings and to verbalize those interrelations, and to speak about happenings and actions and about relationships among human beings. The preconditions for this level include capacities of cognitive representation on a scale broader than stage 2 and the ability to process elementary linguistic techniques.

No existing language entirely represents stage 3 or earlier stages as described above. This means that in the living languages of the world, there is no evidence of “primitive” linguistic structures. Lingering beliefs

about the existence of “primitive” languages in the communities of modern humans are a reflection of prejudice.

Interacting Verbally in Communities of Modern Humans

This stage is documented in the contemporary languages of the world as well as in the stages that have been reconstructed for protolanguages (Proto-Indo-European, Proto-Uralic, and others).

At this stage, the entire panorama of speech sounds that are found in the languages of the world has evolved.¹⁰ Living languages show a vast variety of sounds. For example, in Tahitian, a Polynesian language, only 9 consonantal sound qualities are distinguished. The language with the most consonants in the world is !Xóõ (/Hua-Owani), a Khoisan language, for which no fewer than 117 consonant phonemes have been identified.

In phase 4, all word classes such as nouns, verbs, pronouns, adverbs (e.g., well, truly, often) and others are distinguished. This includes a class of conjunctions to link main clauses or main and subordinate clauses. Gender and number relations are fully developed in the system of grammatical categories.

This stage demonstrates the emergence of full-fledged case systems (with maximal distinctions of 15 cases in Finnish and 23 in Hungarian), complex verbal systems (with distinctions between simple and complex tense categories), fully developed aspect correlations (as in Slavic or Semitic languages), and complex pronominal systems.¹¹

Word order (i.e., elementary syntactic structures) is fully developed, with the elements S (subject), V (verb), and O (object) appearing in various configurations. In the languages of the world, different patterns of word order dominate. Most frequent are those orders with subject-initial position (i.e., SVO in most European languages and SOV in Altaic and most Semitic languages). Verb-initial word order is found in Celtic, Berber, and Polynesian languages. Object-initial word order is of rare occurrence. Languages with a OVS order are Gupapuyngu (Arnhem Land, Australia) and Barasana (Vaupés District of Columbia). One finds an OSV order in Apos (Papua New Guinea).¹²

The lexicon in complex languages is multilayered. The abundant lexical material existing in each language system reflects the cultural

environment of humans in relationship to their natural surroundings. In a given local language, lexical items also reflect the socioeconomic and cultural activities of a given speech community. For example, in Saamic or in Evenki, we find the highly specialized terminology of reindeer breeding. In the Somali vocabulary, for obvious reasons, there is no terminology relating

In the Somali vocabulary, for obvious reasons, there is no terminology relating to reindeer breeding, but this language possesses a special lexicon abounding with terms for camel breeding.

to reindeer breeding, but this language possesses a special lexicon abounding with terms for camel breeding.

The process of a division of labor and handicraft specialization in the societies of antiquity enhanced the elaboration of specialized sections of the vocabulary. In the era of industrialization, with the emergence of modern sciences, the pressure to create new terminologies has increased. World cultures are now confronted with the presence of global networks that require processes of modernization and the elaboration of a sophisticated vocabulary to serve the manifold purposes of electronic communication.

The evolutionary stage (stage 1) representing a simple protolanguage can be postulated for *Homo erectus*, who possessed certain capacities for a limited communicational system. This stage may also have dominated the verbal communication of Neanderthals who, in a later period of existence, might have reached stage 2 of a more elaborate protolanguage. However, stages 3 and 4 are reserved for modern humans. Stage 3 can be assumed for the early phase of *Homo sapiens sapiens*, about 100,000–70,000 years BP (before the present).

Stage 4 must have already emerged before modern humans peopled Sahul (the landmass comprising Australia and New Guinea) circa 62,000 years ago and before the colonization of Europe circa 45,000 years ago. The identification of the period circa 60,000 BP as a *terminus ante quem* is crucial because in the languages of Australia and in the Papuan languages of New Guinea there are no exceptional features that would indicate a seclusive development of language skills in those regions. It is clear from the earliest colonization of the Americas that only the complex languages of stage 4 were introduced. Modern humans entered the North American plains not later than circa 15,000 BCE.

The different strategies used by complex languages to make their grammars operational are known as “language types.”¹³ The emergence of language types is associated with stage 4. Language typology deals with issues of typological resemblances in languages (not with genealogical kinship, as does historical linguistics). The techniques of one type may work in languages that are historically unrelated. For example, Chinese linguistic structures are governed by techniques of the isolating type (see below). The same techniques have shaped the structures of modern English, which has retained only a few morphological elements from its stage of development as an inflectional language (i.e., the grammar of Old English).

Empirical research has provided much insight into the cooperative working of typological techniques. This means that a given historical language operates with techniques of different types, although as a rule the techniques of one type may dominate. The languages of the world may be categorized according to the dominance of one of the following types.

The Inflectional (Flexive) Type

This term indicates the significance of inflection. Case relations as well as phases of verbal action are expressed with the help of grammatical morphemes. What distinguishes the inflectional type clearly from the agglutinative type is the fact that the stem of words may change in the

process of inflection (e.g., a change in the vocalism of the stem, as in English *mouse*: *mice*; a change in consonantism as in Russian *drug* [friend] versus *druzhbba* [friendship]). Most of the Indo-European languages are predominantly inflectional.

The Agglutinative Type

Relations are expressed by means of fixing (agglutinating) formative elements to the word stem. The phonetic structure of the stem does not change in this process. Predominantly agglutinative are Altaic and most of the Uralic languages (e.g., Turkic, Tatar, Mongolian, Komi, Mansi, Yurak).

The Isolating Type

The techniques of this type exclude grammatical morphemes. Relations in the nominal and verbal complex are expressed by syntactic means, that is, through the positioning of lexical items in the syntactic continuum. Chinese is a typical isolating language. In ancient Chinese, isolating techniques are best represented. There is no inflection of the monosyllabic word, in the noun or in the verb system. In modern Chinese, there is some agglutination (as reflected in the existence of two-syllable compound words).

The Incorporating Type

Grammatical relations are expressed by a multitude of formative elements that are suffixed, prefixed, and/or infixes. The word stem can be enlarged by adding suffixes or prefixes, and objectival elements expressing dative or accusative objects (pronominal and nominal) are usually incorporated in the conglomerate of the stem and its extension. In statistical terms, words used in languages of the incorporating type are longer than in languages of other types, and this is due to the multitude of elements that are incorporated.

The linguistic techniques of the incorporating type operate most extensively in the indigenous languages of North America.¹⁴ A high degree of incorporation is categorized as polysyntheticism. This is typical of the structures of languages such as Chipewyan, Seneca, or Oneida. In the Eskimo languages (among them Sirenik in Siberia, Yupik in Alaska, Inuit in Canada, Inuktitut in Greenland), polysynthetic constructions are most elaborate; for example, Greenlandic *aawlisa-ut-issbaR-siwu-nga* (“I try to get something which is suitable for making a fishing tackle”) translates literally as “fishing tool-suitable-obtaining-my.”

Evolution and Extinction

In the process of evolution, many languages have emerged and many have died. The birth of new languages can be witnessed in our days.

For instance, when the old political order of the former Yugoslavia dissolved, the Serbo-Croatian language split into the modern languages of Serbian, Croatian, and Bosnian. However, of the 6,400 languages in the world today, many are endangered. This is true for some 2,100 languages whose speakers are under the assimilatory pressure of a dominant language. Is the process of evolution now primarily directed toward the extinction of languages? Will linguistic diversity ultimately be lost?¹⁵

Two centuries ago, Wilhelm von Humboldt (1767–1835), who was the first to engage in scientific study of Basque, predicted that this language would die out by about 1900. The death of Welsh, the Celtic language spoken in Wales, was predicted for the end of the twentieth century. In fact, both languages are still spoken by more than half a million people. Similar statements have been made about numerous other languages that have survived the predictions of their death.

It is hazardous to make generalizing statements about the crisis of the world's languages by extrapolating from limited conditions. There are regions with a multitude of languages where the local conditions of contact and the impact of conflict vary considerably. It is obvious, however, that the pressure exerted by dominant languages and cultures on local indigenous peoples is the key to understanding why indigenous languages vanish. Among the indigenous communities in Brazil, for example, the continuity of cultures and languages is guaranteed best where contacts with nonnative peoples are reduced to a minimum. English, the prominent vehicle of the globalization process, is often blamed for the mass extinction of indigenous languages.

English, however, is not homogenous. Linguistic variation reaches far beyond the well-known distinction between British and American English.¹⁶ There are many local and social varieties of English, such as Hindish in India, the English of the Australian outback and New Zealand, Ebonics in the United States among African Americans, and dozens of pidgin and creole variations. There are also variants of English spoken in Canada, the Caribbean (especially Jamaica), South Africa, Asia (India, Singapore, Malaysia, etc.), and other locations throughout the globe.¹⁷ English deserves recognition as the one language that has produced the greatest number of historical derivations.

The Death of Indigenous Languages

In the aftermath of the loss of each indigenous language—resulting from the shift of its speakers to another dominant language—cultural identity weakens. As long as the local language is alive, it may function as a shield against the inroads of foreign cultural influences. The moment it dies, foreign cultural elements gain direct access, via the vehicle of the foreign language, to the inner circle of the community whose speakers have become assimilated. There are numerous local communities scattered throughout the world that have lost the language of their

In the aftermath of the loss of each indigenous language—resulting from the shift of its speakers to another dominant language—cultural identity weakens.

ancestors. While these “speechless” societies may retain certain elements of their local cultural heritage, they are progressively absorbed by the cultural and linguistic web of the dominant community with whom they have been in long-term contact.¹⁸

Most “speechless” communities of the world are found in North and Central America as well as in Australia. The Catawba in South Carolina have retained some of their cultural traditions and identify as members of a community that differs from others, but none of the Catawbas speak their own language. Similar conditions prevail in many other Amerind communities in the United States whose members speak only English, such as the Kalapuya in Oregon, the Natchez in Oklahoma, the Miami in Indiana, the Narragansett in Connecticut, and the Powhatan in Virginia.

Many of the Aborigine groups in Australia are also “speechless” or on the verge of becoming so. Knowledge of the local language has faded among the Warrgamay and Warungu in the region of Cairns; among the Gowar, Yagara, and Gabigabi in the region of Brisbane; and among the Awabakal and Dharawal in the Sydney area. For some of these communities, an exact date for the death of the local language can be given. It is known, for example, that the last speaker of Tasmanian, a woman named Truganini, died in 1876.

There are many local speech communities with only a few speakers left. In some extreme cases, we can witness the transition of a living language into a fossil without practical communicative functions. Where only one single speaker is left in a community, he/she can only communicate with the spirit of the ancestors because no one else is left who understands the native tongue. Such are the conditions for the Barrow Point, Biladaba, Dirari, and Gugadj languages of Australia.

The chronological list of extinct languages with the dates of their disappearance is long. Language death has always been an arbitrator in the history of ethnic communities. Recent cases of language extinction are among the Yavitero (extinct since 1984 in Venezuela), Nooksack (extinct since 1988 in the U.S. state of Washington), Kungarakany (extinct since 1989 in Australia), Liliali (extinct since 1989 on the Indonesian island of Buru), Kamassian (extinct since 1989 in Russia, western Siberia), and Mlahsö/Suryoyo (extinct since 1998 in Syria, province of Diyarbakir).

Local speech communities are often embedded in a wider ethnic community with a fading maintenance of cultural traditions. Such a process of transition can be observed among the Manchu in northeastern China. More than 4 million people are known to have Manchu ancestors. Of these, 1.8 million Chinese citizens profess a Manchu ethnic identity. In contrast to this sizable ethnic community, not more than 70 speakers of the Manchu language are still alive.

Similar processes of a gradual loss, first of language and then of culture, are typical of the Hawaiian community. At the time of the “discovery” of the Hawaiian archipelago by James Cook in 1778, more than half a million Polynesians inhabited the islands. Today, there are 0.336 million ethnic Hawaiians, about half of them being the offspring of ethnically mixed parents. Of the ethnic Hawaiians, only 800 have an active

knowledge of their ancestors' language, and nearly 1,000 can still understand it. The loss of the local language finds its parallel in the loss of cultural traditions whose revitalization has become an attraction for the tourist business rather than for many Hawaiians' daily lives.

Indigenous language functions as the vehicle for the perpetuation of an entire fabric of cultural patterns. Therefore, the survival of indigenous languages is critical for sustaining cultural diversity and the continuity of local knowledge. When languages are allowed to die, their unique traditions and accumulated cultural memory are lost to the present and to the future. Moreover, since the structures of any particular language shape one's perception of the world in specific ways, the loss of language diversity can also be seen as the loss of perceptual richness, affecting how people live and interact in the world.

In the essay below, Dr. Duncan considers cosmology and religion, the means through which humans search for an understanding of the universe and of our place in it. It appears that people were watching the skies and speculating about their composition long before the advent of agriculture and the priestly societies. There are philosophers and scientists who firmly believe it is in cosmology that science, philosophy, and theology meet. It is an inspiring, thought-provoking journey.

—Carolyn Neel

Cosmology and Religion: The Human Quest for Meaning

Todd Duncan

Introduction

One of the most profound human emotions is a sense of the mysterious, an awareness that we are part of something much greater than ourselves whose essence we can only dimly perceive. Although the origin of this awareness is lost in prehistory, we can re-create something like the change in consciousness that it must have involved. Simply go outside on a clear, dark night, gaze up at the starry sky, and notice the shift in awareness from a narrow view of your immediate concerns to a cosmic view of yourself as a strand in the vast tapestry of the heavens. Albert Einstein captured the importance of this fundamental religious emotion with these words:

The most beautiful and deepest experience [one] can have is the sense of the mysterious. It is the underlying principle of religion as well as all serious endeavor in art and science. He who never had this experience seems to me, if not dead, then at least blind. To sense that behind anything that can be experienced there is a something that our mind cannot grasp and whose beauty and sublimity reaches us only indirectly and as a feeble reflection, this is religiousness.¹

The widespread experience of the mysterious is a driving force that we can trace as a common thread through human history. Varied responses to that experience—how to make sense of it and answer the questions it raises—have shaped many aspects of human societies. Once an awareness of something beyond ourselves enters our consciousness, it raises questions beyond the immediate: What is this larger universe I am a part of? Does it have a structure and an order I can understand, and is there a specific role for me to play within its order? Was there a beginning to time? If so, how did the universe come into existence from nothing?

The answers that we give to questions such as these define a cosmology, a framework of beliefs about the nature of the universe that

organizes our experience and tells us how we fit within the grand scheme of things. Although we all live within the same universe, cosmologies vary widely from era to era, society to society, and even individual to individual. But all are responses to the same fundamental emotion of mystery and wonder that we experience in the presence of the universe and in our attempts to come to terms with it and harmonize our lives with it. Often there is a close mapping between a people's cosmology and the structure of their society. We look to the broader universe to find a context for ourselves within which to situate the details of our lives. In the words of Louise B. Young, "in human affairs an idea is a greater moving force than any physical influence. . . . So the shape of our future will depend to a large extent on our understanding of our role in the cosmic process."² In the rest of this essay, we will investigate the broad trend of how this impulse to understand our role in the larger cosmic process has helped to shape human societies.

Earliest Cosmologies

Because religious feelings emerged long before recorded history (probably even before symbolic language), we must rely on educated speculation guided by indirect evidence to help us re-create their earliest expression. Perhaps the longing for a meaningful place within the context of something greater than ourselves first appeared a few hundred thousand years ago as a vague sensation like hunger or thirst. Was the sensation connected to an awareness of time and death and the reality of events occurring before and after an individual life? Was there an awareness of making choices and an accompanying sense of morality, a feeling that choices can be "right" or "wrong"? What did these experiences feel like, and how were they expressed as they first emerged? Perhaps the closest we can come to empathizing is to imagine experiencing the feelings as we do now but without words to crystallize and label them.

We can speculate that the first cosmologies were a natural extension of the immediate experiences and surroundings of the people who created those cosmologies. Their nomadic lifestyles, foraging (and sometimes hunting) food in small groups, must have meant a very concrete and intimate connection to other people, animals, plants, and forces of nature. Some aspects of this environment were naturally more familiar and accessible than others: fruits eaten on a nearly daily basis, for example, would be much more familiar than those encountered only rarely, and immediate tribe members must have seemed more real than distant tribes encountered once a year perhaps. In this setting, one can imagine that the first stirrings of awareness of a world beyond immediate experience amounted to just a small step beyond these concrete experiences. As David Christian describes, "Modern studies of small-group religions suggest that the earliest human communities thought of the entire cosmos as bound into webs of kinship. . . . The supernatural world may also have been seen as a distinct but accessible realm—

almost like a separate tribal territory, with whose occupants one could negotiate, fight, or intermarry.”³

With the emergence of symbolic language (perhaps 150,000 years ago), the articulation and sophistication with which these feelings were expressed must have increased. Perhaps the early process of developing religious feelings could even be viewed as paralleling the growth of language, a transition from concrete to abstract, symbolic representations.

In any case, symbolic representation and language give us a chance to pick up the thread and start to find evidence of the internal world of our ancestors’ thoughts. Every culture is unique in some ways, so extrapolation based on observations of present-day hunter-gatherer societies (e.g., the San people of Botswana and the indigenous Australians and Americans) is limited and may be misleading. And the point where we can even begin to pick up the thread of religious feelings must already leave out a significant and rich history.

Still, we *can* pick up the thread by looking at the available material clues and make reasonable guesses about the inner world of the minds who produced them. Evidence of symbolic and ceremonial acts revealing a rich inner world is provided by middle Paleolithic artifacts and paintings dating back to at least 70,000 years ago in southern Africa.⁴ Such early signs of ceremonial practices beyond the necessities for survival are widespread, though of course we must be cautious of overinterpreting their meaning from a modern perspective. Findings in the Shanidar caves of Iraq (dating to about 60,000 years ago) and a 28,000-year-old Cro-Magnon site discovered near Moscow suggest ceremonial burial, which implies a concern for the well-being of the dead.⁵

Is there a common theme to these early expressions of religious emotions? Once again we must be cautious of overgeneralizing, but anthropological observations combined with the earliest archaeological evidence suggest that early expressions took the form of animism. An animist perspective views all objects in our surroundings as alive, with personalities and motivations analogous to what we humans experience. This perspective fits naturally with the hunter-gatherer way of life described earlier. Human interactions with the natural world were direct and concrete: individuals interacting with other *individual* life forms, whether human, other animal, object, or force of nature. This view of the structure of the universe is evident in the artifacts reflecting the structure of their lives: how they searched for food, related to each other, performed burial rituals, etc. A glimpse of this way of life is captured by Edward Harrison:

A magic universe each day was awakened by the Sun spirit and at night mourned by the Moon spirit. It was a universe of starlike campfires stretching across the night sky, of chromatic sky spirits manifesting in rainbows, sunsets, and northern lights, of mighty

Perhaps the early process of developing religious feelings could even be viewed as paralleling the growth of language, a transition from concrete to abstract, symbolic representations.

earth spirits rumbling beneath the ground and spewing forth from volcanoes. . . . The sudden noise, the fallen tree, the shaft of light piercing the forest gloom, the rising river, the lowering sky, the hurtful stone, and each incident of every day was the natural outcome of incarnate spirits pursuing their personal interests. It was a numinous world of the kind fleetingly glimpsed by children in spine-tingling fairy tales.⁶

States and Abstract Cosmologies

Perhaps not surprisingly, a major transition in cosmology and religion accompanied a corresponding transition in way of life. With the emergence of agriculture around 10,000 years ago and the concentration of people into cities roughly 5,000 years ago, along with the increased mobility provided by the domestication of animals such as horses and camels, significant accumulation of food and other material wealth became possible. This must have been part of a profound shift in lifestyle. No longer did everyone interact with nature directly to acquire the immediate necessities of life. Wealth in the form of food and other material goods could

be stored, transported, and accumulated. Denser concentrations of people and of goods to be distributed led to the emergence of more complex social structures. Social roles became more divided, specialized, and hierarchical, and for many people wealth began to be acquired not through direct interaction with individual beings in nature but through social interactions embodied in institutions instead of individuals. Power became more concentrated and abstract. Many human societies began moving toward the centralized and hierarchical social structure of states that we see today.

New cosmologies emerged in parallel with these changes, shaped by the new social structures and in turn helping to shape social evolution. The old cosmic order was an extension of a largely egalitarian society of individual humans interacting with individual beings in the natural world. The new hierarchical social structure, in which people were beginning to interact with abstract, symbolic *institutions* instead of individuals, naturally extended to a new cosmic order. Just as rulers were now remote from most people and their status was consolidated by tributes and monumental architecture, gods became more awesome, remote, and symbolic, consolidating the power and meaning that once resided in the individual spirits of every object in nature.

As the reach of individual states grew, so did the reach of their associated cosmic order. Univer-

sal religions seem to have first emerged at the same time as universal empires, around 3,000 years ago. As David Christian writes:

One of the earliest religions of this type, Zoroastrianism, appeared in the largest empire of the mid-first millennium BCE, that of the Achaemenids, and at the hub of trade routes that were weaving Afro-Eurasia into a single world system. Indeed, most of the universal religions appeared in the hub region between Mesopotamia and northern India. They included Zoroastrianism and Manichaeism in Persia, Buddhism in India, Confucianism in China, and Judaism, Christianity, and Islam in the Mediterranean world.⁷

Thus, we see that at the same time the foundations emerged for the state-based socioeconomic structure we have today, the foundations for modern religions connecting this social order to the mystery beyond the everyday world were established as well.

Modern-Day Cosmologies

In contrast to most of human history, a distinguishing feature of cosmology in the last few hundred years is the split between its scientific and religious aspects. Most people today practice versions of religions that emerged out of the traditions described in the last section. These religious traditions carry with them associated models of the structure and arrangement of the universe (although these descriptions now tend to fade into the background; the focus is more on personal values and instructions for behavior, separated from the order of the universe that supports these values and instructions). At the same time, scientists who focused more on uncovering the structure of the universe (and less on the morals or values associated with this structure) have acquired a wealth of new evidence about the nature of the universe that has led to the emergence of cosmology as a field of science in its own right.⁸

While scientific and religious cosmologies are often viewed in conflict, a historical perspective helps us see them as part of the same trend of coming to terms with the mystery behind our existence. The scientific process is an extension of the same sort of exploration that we speculated must have occurred in early hunter-gatherer societies: extending the familiar world to answer questions about things that are beyond the familiar. The process we use today may be different, but the basic goal of grappling with the vaguely articulated meaning behind things is still the same. We still seek a framework for a general set of answers to questions about who we are and how we fit in.

Scientific evidence has broadened our awareness of the cosmos far beyond what our hunter-gatherer ancestors knew about and even far

While scientific and religious cosmologies are often viewed in conflict, a historical perspective helps us see them as part of the same trend of coming to terms with the mystery behind our existence.

beyond the cosmos known to our recent ancestors a century ago. Where once the lands of nearby tribes or other nations on our planet seemed to fade away at the edges of the universe, we now have concrete knowledge of a cosmos almost incomprehensibly vast: entire worlds beyond the Earth, countless stars beyond our Sun, and islands of stars like our own Milky Way that are so distant their light takes billions of years to get to us across vast reaches of space.

We also have now a scientific timeline of the history of the cosmos that places human history in a much broader context of time. To make this context for human history concrete, consider this:

If your outstretched arms represent the entire 13.7 billion year history of the universe, with the beginning of the universe at the tip of your right middle fingernail and the present day at your left middle fingernail, then the length of time humans have existed occupies only a sliver of fingernail, less than a millimeter thick. Trim your fingernail slightly and you remove human existence from the timeline, but leave the vast majority of cosmic history untouched!⁹

This science-based expansion of our awareness beyond what our ancestors could dream of has provided a unified intellectual description of our history and our surroundings that goes far beyond our immediate experience. This is another profound shift in the thread of developments driven by our awareness of the mysterious because it provides a common backdrop within which to think about the many different individual cosmologies among various cultures, past and present. Perhaps the next great advance in human culture will occur as this unifying framework of cosmic structure and history allows us to see individual, local cosmologies as ways of metaphorically coming to grips with the beauty and sublimity of the mystery behind existence. It will allow us to see that something real is there, even though any of our individual descriptions are incapable of capturing it completely.

This perspective is nicely summarized by primatologist Jane Goodall:

There are many windows through which we can look out into the world, searching for meaning. . . . Most of us, when we ponder on the meaning of our existence, peer through but one of these windows onto the world. And even that one is often misted over by the breath of our finite humanity. We clear a tiny peephole and stare through. No wonder we are confused by the tiny fraction of the whole that we see. It is, after all, like trying to comprehend the panorama of the desert or the sea through a rolled-up newspaper.¹⁰

We may never know the true nature of the universe and our place in it. But insights emerge as we trace the history of the search for meaning and view different cosmologies as different ways of exploring and interpreting what is fundamentally the same basic mystery. Perhaps the opportunity to combine the views from a wider variety of windows

will allow us to look deeper than ever before into the meaning of our existence.

Few of us can imagine humans without tools, forced to depend solely on our fingers and teeth to satisfy our needs for warmth, shelter, food or for transporting materials and small children, etc. As Dr. Kay illustrates, the same is true of many other species, such as ants and beavers. In the essay below, Dr. Kay considers the nature of tool-making and technology when placed in the context of the “natural world.” Together with the essay by Dr. Burns that follows, these pieces offer great insight into the development of human tool-making and technology.

—Carolyn Neel

Humans, the Tool Makers

Marvin Kay

Technology, *n.* 1. Industrial science; systematic knowledge of the industrial arts. 2. Terminology used in arts, sciences, or the like. 3. Applied science.—**technologist**, *n.*

Technological, **technologic**, *adj.* **a.** Pertaining or relating to technology; as, *technological* advance or problems. **b.** Relating or due to advance in technology; esp. in application of scientific knowledge, methods, or research to the industrial arts and the fields of manufacture and building; as, advances in technological productivity. **c. Econ.** Resulting from improvement in technical processes which increases the productiveness of machines, eliminates manual operations or old industries, or the like; as, *technological* unemployment.—**technologically**, *adv.*

(Definitions from Merriam-Webster Inc.
Webster's New Explorer College Dictionary.
Springfield, MA: Federal Street Press, 2003.)

Sir Kenneth P. Oakley, the debunker of the Piltdown hoax, in his book *Man the Tool-Maker* affirms the primacy of man as a maker and user of technology.¹ Oakley's view is widely held and seemingly is beyond reproach, for surely humans create the material world or “built” environments of our cities, smaller towns, farms, dwellings, factories, roads, seaports, and other infrastructure. We also have a vested interest in balancing tool efficiency with conservation of scarce material resources. And it is hard to imagine another species so conscious and deliberate in its technological choices or whose material record so emphatically speaks of intrinsic intelligence, thinking, planning, and the most human of all characteristics, the artful dodge, deliberate deception, or conjuring about art, literature, and the cosmos. In sum, while one cannot regard lying as the oldest human profession, it was a necessary precondition. Likewise, technology, in all its myriad forms, is quintessentially human and defines us as separate from other life forms. Or so it might seem.

We must, however, take a larger view of tools and technology. Indeed, how can one argue against, say, a sea otter as a tool user after watching

it swim on its back and smash a clam shell on its stomach with a rock? Or a beaver impound a stream and build a sturdy lodge in the resulting pond of sticks, logs, and mud and with an underwater entrance passage into an *engineered* central sleeping chamber? Moving down the phylogenetic ladder, it is readily apparent that other creatures contribute to structuring their own environments, for instance, paper wasps and hornets make their nests of a paper-like material that they make from saliva and wood fragments, while spiders construct intricate webs to trap prey.

At the low end of this scale, my favorite example is well known and now understood by Plains archaeologists, thanks to the research of Larry Todd and his students at Colorado State University, Fort Collins. In surveying (or surface reconnaissance of) high plains prairies for archaeological sites, one must look at anthills. Why anthills? The main reason is that in a grassland there are few subsurface exposures to check for artifacts, and ants—harvester ants to be precise—often collect and display them atop their anthills, just waiting, it seems, for our inspection. The question that Todd and his students explored is, what would possess harvester ants to collect and display inedible artifacts? The most notable of these artifacts are brightly colored glass beads a little bigger around than a pinhead, or what are called seed beads. Given the size of an ant, moving a seed bead is a pretty big deal.

The general findings of this research are relevant to my purposes here. It turns out that after harvester ants collect inanimate objects from the territory about an anthill, they move them into and out of the anthill during day or night depending on how well they retain heat.

It turns out that after harvester ants collect inanimate objects from the territory about an anthill, they move them into and out of the anthill during day or night depending on how well they retain heat.

Brightly colored but generally dark seed beads absorb heat. These are often discovered on an anthill's surface during the day and appear to have been left deliberately to absorb heat. They then are brought into the anthill to warm it at night. Conversely, light-colored seed beads and other similar small objects with the appropriate thermal characteristics to deflect heat are left

on an anthill's surface in the evening and are brought into its inner passages to cool them during the day. Heat regulation drives the ant to get and move these transportable objects into and out of its anthill. Quite apart from being either artifacts or ecofacts (or objects of nature), the objects are used if not fully regarded by the harvester ants as simple tools. These require no further modification to satisfy a vital physiological need.

These examples hardly scratch tool use among other animals, but I need not explore them more fully. Rather, my purpose is to identify some principles behind tool using by humans or other critters. More generally, I regard tool-using behaviors as a more inclusive concept that embodies the overall linear process of production, use, repair, recycling, intentional discard, and accidental loss, or what is described as a production chain and is crucial to engineering design assessments (for a few archaeological studies and applications, see the works listed in

the bibliography, particularly those by Peter Bleed and David P. Braun). I then make distinctions among human and other animal technology.

Technology and Tool Use Principles

Technology is extrasomatic, or nonbiological, and not part of the biology of the creating or employing organism. The most basic and fundamental technological systems address or satisfy physiological needs, on the one hand, and may be imbued or designed to connote symbolic content or meaning to makers and users alike, on the other. Tools afford a mechanical advantage that multiplies or extends the somatic capabilities of the organism, regulate heat (as is true of a hot water bottle or a seed bead for a harvester ant), or in some other way enhance performance and satisfy other physiological needs. They may vary too from the transportable to the fixed and stationary.

With these principles in mind, exactly what satisfies the definition of a tool is debatable if one goes to a logical extreme. An animal path or burrow need not be regarded seriously as a tool or even as a stationary facility or fixed modification to a landscape, even while either might make travel easier or safer. They seem to fall more into the category of by-products of habitual behavior (instinctual or learned) that constrain or modify a landscape or its substrate. So, if one wished, it would be logical to exclude too the beaver den and dam, the wasp or hornet nest, the spider web, and so forth. While deigning these exclusions as logical possibilities, I must confess to favor a fuzzy logic to this question; to wit, some objects are difficult to uniformly classify or require placement in an indefinite, or catchall, group. There is simply an uncertainty in the classification of facilities: if for all purposes and occasions are these strictly tools more so or exclusively than the stationary by-products of habitual behavior? Another application of fuzzy logic is that I am far more comfortable in classifying harvester ant manipulation of small objects with discrete thermal properties as tool use, whereas I would not opine an equal status to a bison wallow or to an elephant dusting itself to ward off insects; the latter more properly are examples of habitual behavior but obviously no less so than the harvester ant's. Indeed there is a parallel logic, as facilities exist that would seem to apply equally well to a bison wallow and a cattle dipping station. So should they both qualify as being technological in nature? Habitual behavior would underlie a deer or elk sharpening its antlers on a rock face, true enough. But would the rock face constitute a facility, a tool?

Classification and proper use of terms is fundamental to science. Yet it is in life where terminology is as vital as is the principle of classification. The consequences of racial terminology go well beyond the little science evident. Is Pluto a planet or merely a minor subplanetary body? The terms matter in either case because they stand as a reference to a larger reality, or perception, shared dearly by many regardless of any empirical measure of objective truth. The same, I submit, might be said of tools and tool using. Uncertainty is troubling to many users of science.

But it is uncertainty that drives science. Uncertainty is why our classifications of tools and tool using are partial or incomplete and are subject to change as knowledge improves.

Production Chains

A broad view to tool using allows development of a primitive theoretical model, or paradigm, of tools and technology more generally. The first step in this model opposes two dimensions, production mode dichotomized as single-step and multistep against animal group of nonhuman or human.

Single-step production is one in which resource procurement predominates when referring to a transportable object because it is not further modified for use. When speaking of stationary facilities, using them for a specific purpose, or purposes, alone transforms them. Thus, in either case usage for one or more purposes defines single-step production technology; elements of this type are often called ad hoc or expedient. Damage or breakage most commonly results in rejection of ad hoc or expedient technology, whether stationary or transportable, because repair does not normally occur or is simply insignificant.

Multistep production typifies more complex technology, whereas complexity strictly refers to a linear progression of commutative, or invariant, operations. These operations define essential and necessary procedures to create, maintain, or recycle technology; within each of these steps the order in which other technological processes are done is arbitrary, or noncommutative. Multistep production technology more commonly is called patterned, or shaped, as opposed to ad hoc and expedient. Multistep production always begins with material or resource procurement and then object manufacture; item rejection for any reason at these or subsequent steps is common and predictable, even when not expected.

These distinctions may seem at first glance to be almost too obvious and simple. They also may seem overly general and too inclusive, as almost anything might fit into one or the other. Their simplicity and inclusiveness, however, are their strengths and have long been recognized as such by archaeologists. An early and still relevant application is that of William Henry Holmes,² who cast a guiding light on production chain studies that still burns bright today. The utility of production chain analysis is, as Holmes recognized, that it gets us closer to the reality of technology and tool use. Technology represents and most profitably is viewed as dynamic and responsive to the needs of producers and users. The fact that we can identify a logical, linear progression when speaking of technology production, use, and discard allows us to empirically assess and compare behaviors and intellectual capability at discrete points in the performance histories of makers and users. When those insights are added to time and space distinctions that govern archaeological science, we have a repertoire of unified approaches to compare systematic differences in behavior and to evaluate their underlying causes.³ To what extent multistep production incorporates symbolic

thought typical of human speech is debated even for those species clearly within our ancestral line or co-occurring with it.⁴

Humans and Other Animals

Drawing on the few examples already cited, tool use among nonhuman, human, and our immediate or more distant ancestors is better known to satisfy physiological needs for shelter, food, water, and heat regulation. Single-step production technologies dominate the transportable tools of nonhuman animals. They undoubtedly were far more common too among our ancestors and other primate relatives than we have recognized from the archaeological record. Ancient stationary facilities, of single-step production, suffer a similar fate and are poorly or rarely recognized as such. Multistep production “technologies” are evident among nonhuman animals. Should one overlook the terminology plus the habitual behavior they mostly represent and focus upon performance criteria, these items would be as amenable to a production chain analysis as any fully acceptable similar multistep technology; as such, these items represent a direct measure of performance capability among species and species-specific differences regardless of underlying causes.

In this essay, Dr. Burns considers the role of technology in world history as humans become increasingly adept at developing technology to master their environment and overcome difficulties. Ultimately, we develop technological solutions to problems caused by our use or misuse of technology. The transition from simple digging sticks to complex computer-controlled weapon systems is an exciting journey to any of us who love our computers or our automobiles.

—Carolyn Neel

Technology in World History

William E. Burns

Humans are particularly dependent on their ability to design and produce tools. The attempt to manipulate, coerce, and improve on nature through technology is a constant human characteristic; no human society has existed without developing some forms of technology. However, technology, which we define as the art of producing and using tools, predates humanity. Some species of birds and animals use tools; for example, sea otters use rocks to smash open clam shells. A few species, including chimpanzees and New Caledonian crows, have even been observed to fashion objects into tools. Some of the earliest evidence of human societies is also evidence of their technologies: flint knives, bone needles, and other devices. Fundamental areas of life in which humans from early on sought technological solutions include obtaining, preserving, and preparing food; transportation; housing; and organized violence.

Technology and Environment

Humans have been able to adapt to a broader range of environments than any other mammal through the use of environment-specific technology. Arid environments, such as deserts, have called forth technologies based on the maximally efficient use of water resources, as the Garmantes of the Sahara dug irrigation canals out of limestone to tap underground springs. Isolated islands in the South Pacific were knit together into units capable of supporting complex human societies by the development of shipbuilding and navigation. The degree of technical ingenuity displayed by a society is not necessarily indicative of its degree of civilization in the sense of urbanization. Some of the most difficult places for human beings to live, such as the frozen tundra, can only support a small population but make immense demands for technology. The Arctic was opened by the oil lamp, which enabled long-distance hunting expeditions in the winter when the days are very short. Northern peoples, faced with difficult terrain and scarce resources, have shown great ingenuity in transportation technology, such as skis and snowshoes, as well as the ability to make maximum use of the resources they have, such as using polar bear teeth for fishhooks.

Some remote societies such as the Inuit of the Arctic used small-scale technologies to survive in hostile environments rather than large-scale technologies to reshape their environments. The densest early human societies, by contrast, in the great river valleys of Mesopotamia, Egypt, northern India, and China were supported by irrigation systems that channeled water over large productive agricultural areas. The Chinese placed such value on irrigation as to ascribe it to the legendary sage-emperors, while a Mesopotamian legend claimed that humans had been created by the gods to work on their canals. With large labor reserves to draw on, early societies could carry out large technological projects for economic reasons as well as for cultural or religious reasons, such as those remarkable works of engineering, the Egyptian pyramids.

Technological Innovations

One of the major questions in the history of technology is whether new technologies are usually invented once and spread from their point of origin or whether similar problems result in similar solutions in different settings, arrived at independently. A classic example of the different relations between technologies in different places involves the appearance of several originally Chinese inventions—paper, gunpowder, the

compass, and the printing press—in late medieval Europe. Paper and gunpowder came by transmission routes that can be fairly well documented. Paper was invented in China several centuries before the Common Era, and knowledge of its making was transmitted to the Islamic world in the eighth century CE. From Islamic Spain paper made its way to Latin Europe. Arab culture also seems to have been the intermediary by which the use of the mar-

One of the major questions in the history of technology is whether new technologies are usually invented once and spread from their point of origin or whether similar problems result in similar solutions in different settings, arrived at independently.

iner's compass reached Europe, while European knowledge of gunpowder was a product of the increasingly close relation of the Eurasian civilizations in the age of the Mongol empire. However, printing seems to have been an independent European invention.

However, many technology transfers lie on a continuum between direct transmission and independent invention. The mere knowledge that a technical problem has been solved can spur others to duplicate the solution. Porcelain, invented in China, found a ready market in seventeenth-century Europe, spurring Europeans to independently discover the process for making it in the early eighteenth century. Technological advance can also be spurred through emulation even if the technologies involved are radically different. Eighteenth-century British textile manufacturers were eager to compete with the cheap and colorful cotton fabrics of India, but the industrial processes they invented were very different from Indian handwork.

Another major question concerning technological development is the relative importance of incremental improvements, often anonymous,

Left: Chintz coverlet from the Coromandel Coast, India, about 1770. Right: English chintz, eighteenth century. (Private Collection/Mark Fiennes/The Bridgeman Art Library/Burstein Collection/Corbis)

in existing technologies and qualitative innovations. While qualitative innovations are usually the most dramatic, a stream of improvements is often required for a technology to reach its full potential. The telephone, invented by Alexander Graham Bell in 1876, in its earliest incarnation could only transmit across short distances. Subsequent and much less publicized inventions such as the loading coil and switchboard were needed to make the telephone a ubiquitous form of communication.

Technologically Creative and Technologically Conservative Societies

Technological advances have played an enormous role in economic growth. Technological advance that brings about improved productivity underlies the most fundamental economic expansions, from the invention of agriculture to the development of the Internet. One notable example was the rise of more efficient techniques of irrigation and better tools for wet rice cultivation in medieval China, which led to the expansion of its agriculture and the growth of its population. Another was the European and eventually the global Industrial Revolution, which has led to continuous economic expansion. Technological change is the easiest way out of the so-called Malthusian trap, by which increases in productivity are absorbed by increases in population and thus do not improve the standard of living for ordinary people.

Some societies have been more open to technological changes, whether of indigenous or foreign origin, than others. The reasons for these differences are disputed by historians, sociologists, and economists. In some places, governments or other authorities have taken specific measures to promote or suppress particular technologies, as

seventeenth-century Japan suppressed gun making. However, the reasons for technical advances and declines are usually not so clear-cut. The explanations put forth range across economics, politics, culture, and religion. For example, it has been argued that the ancient Greeks accomplished little in technology to match their achievements in science because they regarded manual labor as degrading, while medieval Europeans advanced technologically because they believed that God wanted them to master the physical world.

Social change has led to changes in technological creativity. These changes have not always affected all technologies in the same way. The fall of the Roman empire led to a pronounced technological regression in large-scale projects, such as civil engineering, hydraulics, and road building. It would be well over a millennium before Europeans matched some Roman achievements in these areas. However, medieval Europe far surpassed the Greeks and Romans in such small-scale technologies as horse collars and mills to more efficiently exploit the power of muscle, wind, and water. China in the northern and southern Song dynasties was the most technologically dynamic society on earth, but after the Mongol conquest in the thirteenth century it lost much of its capacity to innovate. The great water clock of Su Sung, built in 1087 and the most sophisticated timekeeping and astronomical device to date, was dismantled, found no successors, and eventually disappeared from memory. Even Chinese interest in Western clocks during the seventeenth and eighteenth centuries spurred no desire to emulate them. Britain, the technological leader among Western countries in the late eighteenth and early nineteenth centuries, was surpassed by Germany and the United States by the late nineteenth century.

The Rise of Technological Professionalism

Although persons known for their technical skill and inventiveness had long existed in numerous societies, the development of an organized profession of civilian technological specialists or “engineers,” with accompanying institutions, began in eighteenth-century Europe. Until that time, the term “engineer” had been used primarily in military contexts to refer to an expert in fortifications and sieges like the famous French fortress builder Sebastien de Prestre de Vauban. The broadening of the concept of engineer to include civilian specialists was part of a process by which science and technology had been drawing closer together during the scientific revolution of the seventeenth century. Such scientific ideas as precise measurement and repeated experiment were influencing the culture of technology, and engineering was becoming a more learned discipline. The imposition of the “scientific” or “rational” way of doing things on Europe’s traditional manufacturing cultures was fraught with difficulty. Many texts, such as the famous work of the French Enlightenment, the *Encyclopedie*, spread knowledge of the best technical practices of the day rather than encouraging innovation.

The two most technologically advanced societies of the eighteenth century, Britain and France, saw the engineering profession develop in

startlingly different ways. In France the engineer, whether military or civilian, was usually a state employee and, increasingly, one trained in a state institution such as the famous School of Bridges and Roads, founded around 1747. The traditional European university had little interest in technical advance, leaving a gap for new institutions. Germany developed a similar, although more decentralized, system of technical education than France's with the rise of Mining Academies. British engineers were more likely to be associated with entrepreneurs than with state organizations and were often self-taught or trained by apprenticeship rather than institutionally educated. The British effectively used voluntary associations dedicated to technological progress. The Royal Society, Britain's leading scientific society, recognized what would now be considered purely technical as well as scientific achievements, awarding its highest medal, the Copley Prize, in 1759 to John Smeaton, who is also credited with coining the term "civil engineer." Although British engineers often moved in the same social and intellectual circles as scientists, they made fewer contributions to science than did French engineers, and the subsequent development of the profession has been more influenced by the French model.

The driving force in British industrial technology was not the state but rather private capitalist enterprise. British manufacturers also looked to science and technological improvement to provide them with ways of making more profitable products. James Watt's development of the separate condenser for the steam engine, which enabled steam technology to come into wide use, was financed by entrepreneurs, and the state took little direct interest in technology except that with direct military or naval applications.

From Societies with Technology to Technological Societies

With the dramatic technological developments of the Industrial Revolution and the nineteenth century, societies in the West and throughout the world became aware of the importance of technological development for national power and wealth. At the same time many technologies were growing more complicated, out of the intellectual reach of the illiterate and scientifically untrained. Some of the most important new industries of the late nineteenth century were dyes and pharmaceuticals, which required advanced knowledge of chemistry. One result of these circumstances was the rise of technological education. Germany took the lead in developing technical education outside the established universities with the development of the *Technische Hochschule*. The British model of learning by apprenticeship became outmoded, although Britain's failure to adjust to the new reality is sometimes blamed for the loss of its early technological lead.

Two nineteenth-century inventions, the railroad and the telegraph, contributed the radical technological reshaping of space and time that is characteristic of modernity. The railroad enabled people to move overland at faster speeds than ever before, while the telegraph made

The new obsession with speed that the railroad brought can be seen in the popularity of Jules Verne's novel Around the World in Eighty Days and subsequent improvements in transportation technology, most dramatically the airplane, which also reshaped human relations.

communication over distance effectively instantaneous. So rapid was the railroad that it made necessary the creation of a standardized temporal regime embracing the world: standard time. The new obsession with speed that the railroad brought can be seen in the popularity of

Jules Verne's novel *Around the World in Eighty Days* and subsequent improvements in transportation technology, most dramatically the airplane, which also reshaped human relations.

One aspect of the cultural centrality of technology in the nineteenth century was increased interest in the individuals responsible for technological innovations, or inventors. The ascription of technological advances, or inventions, to specific individuals is a relatively recent develop-

ment. Famous inventors, individuals such as Benjamin Franklin, James Watt, and, later, Thomas Edison, were put forth as role models for boys. (The idea of the famous inventor has been heavily gendered.) The culmination of the cult of the engineer was a short-lived movement for technocracy, rule by engineers rather than politicians. Similar ideas were endorsed in the early twentieth century by leading intellectuals such as the economist Thorstein Veblen and the writer H. G. Wells as well as by influential Marxist regimes.

Technology was also a key component of the dominance that European and Western society was able to attain and maintain over the rest of the world beginning with the Spanish invasion and conquest of the Americas in the late fifteenth century and the sixteenth century and intensifying and continuing into the twentieth century. This was expressed militarily by the superior force of the nineteenth-century Western technologies of metal steamships, rapid-firing guns, and telegraphic communications and economically as indigenous technologies were replaced by Western ones. The technological expansion of the West often even preceded its political and military expansion, as the rifle displaced the bow among Native American groups before these groups were subjugated by Western societies or extended to societies such as Japan, which retained their political independence while adopting Western technologies. (Technical transfers were not always one way. The adoption of corn, an originally American crop, by European settlers was accompanied by adoption of much of the Native American technology for growing, harvesting, and preparing it.)

Technological superiority was also central to the development of the ideology of Western superiority that accompanied imperialism, particularly in the nineteenth century. The technological superiority of European and European-offshoot societies such as the United States were seen as evidence for the fitness of these societies to rule others who were viewed as "primitive" or "stagnant." While Indian technology in the eighteenth century and the early nineteenth century had found many British admirers—even the Royal Navy commissioned Indian shipbuilders to build vessels—after India had been incorporated into the British

Empire and many Indian industries had been destroyed by British competition and discriminatory British policies, British observers usually described Indian technology as primitive.

The late nineteenth century saw some non-Western societies begin to compete and even innovate within the tradition of Western technology, a process that would expand and continue through the twentieth century and into the twenty-first century. The most notable cases are in eastern Asia, led by Japan, South Korea, and China.

Technology and Modernity

Postindustrial revolution society differs from all previous societies in human history in the pace of technological development. New technologies are introduced continuously, and no one who lives to adulthood lives in the same technological world he or she was born in or grew up in. Even different age cohorts living at the same time have diverging technological experiences; witness the endless American jokes about parents relying on their children to program their consumer electronics. The cultural impact of the society of continuous innovation can be seen in the twentieth-century rise of the genre of science fiction, which despite its name is frequently more concerned with technology than science.

Even different age cohorts living at the same time have diverging technological experiences; witness the endless American jokes about parents relying on their children to program their consumer electronics.

The age of the individual inventor as technological hero has been succeeded by that of corporate, state, or university research-and-development and collaborative endeavors, of which the archetype is the invention of the atomic bomb by the organized hierarchical military group known as the Manhattan Project. The ability to absorb or generate new technology is a key measure of the success of modern societies. Both liberal capitalist and most Marxist societies in the twentieth century treated fostering technological advance as a public duty, although fascist and conservative regimes were more ambivalent. Postcolonial societies have often engaged in prestige projects that have proven unproductive, such as Egypt's Aswan dam.

The dominance of technology in modern society has not gone uncriticized. Entertainment technologies, most notably television and video games, have been accused of debasing culture. Advanced technology, by separating people from nature and primary production, has been condemned for its alienating effects. On a deeper level, the alleged tendency in modern society to view all problems as technological in nature, to be solved by technological means, has been criticized by humanists, philosophers, and theologians.

Most contemporary hostility to technology, however, has been motivated by less rarified and philosophical concerns. The unprecedented devastation of the world wars of the twentieth century, culminating in the atomic bomb, has led to fear that technological destructiveness cannot be checked. The invention and testing of the even more destructive

hydrogen bomb in 1952 for the first time brought to consciousness the possibility of the destruction of the entire human race, indeed of all living things on the earth. The end of the Cold War led to diminished concern with the possibility of extermination, but the thought of advanced technology in the hands of terrorists provokes anxiety. Outside the world of purely destructive technology, the fear of the environmental destructiveness of a technological society has increased with the growing evidence for global warming and the shrinking of the ozone layer. The dependency of modern society on its advanced technology is also a source of fear, as people imagine themselves thrown back on technologically primitive strategies of survival in the wake of a global collapse, such as that envisioned in the Y2K scare of 2000.

Beginning about 12,000 years ago in various parts of the world, people began, in slow steps, to adopt a new (and less secure) method of feeding themselves. In the nineteenth and early twentieth centuries, historians and anthropologists considered the development of agriculture as “progress.” After analyzing their bones, we now realize that prehistoric hunter-gatherers had a healthier diet and probably a more satisfying, egalitarian social organization. Farming required cultural adaptation, sometimes including a new, more complex social organization. Dr. McGeough examines the beginnings of agriculture, which is in fact the beginnings of the world we know.

—Carolyn Neel

The Origins of Agriculture

Kevin M. McGeough

The emergence of agriculture is a scholarly problem that is more complex than may appear at first glance. Farming in the twenty-first century is a relatively successful means of reliably providing a variety of food types to a large population. This, however, was not always the case in the thousands of years over which agriculture developed around the world. There are in fact a number of reasons why switching to an agricultural regime would have been undesirable and problematic for those involved in the initial transition.

Archaeological evidence of the earliest agriculturalists has demonstrated that a switch from hunting and gathering to farming significantly decreases the diversity of food choice available to the community. Physical anthropologists (who study ancient human remains) have demonstrated that the decrease in choice of what to eat led to significant nutrition and health problems. Less diversity in food choice also would have impacted the taste of food in general and the social enjoyment that accompanies a good meal.

A common misconception is that agriculture is more secure than hunting and gathering. Over the long term this is certainly true (after agriculture is well established it can securely feed a larger population), but in the initial switch to farming a bad harvest (perhaps caused by drought, locusts, or poor management strategies) could put a community at risk of starvation. Stereotypes of hunter-gatherer lifestyles suggest that this is a dangerous and unstable economic strategy, but ethnographic studies show that this is far from the truth. The mobility of the hunter-gatherer lifestyle allows for rapid and dramatic transformations in food-acquisition strategies.

The work of gathering food is far less difficult in a hunter-gatherer regime than the work involved in intensive preindustrial agriculture. Economic historians consider drudgery to be a major constraint on the types of economic activities that people engage in. The idea is simple: the more difficult and/or boring the work, the less likely people will want to do it. From this perspective, it is difficult to understand what would encourage people to take up a difficult subsistence practice like farming.

Petroglyph of dogs running down two large steppe animals. Helankou Rock Engraving Preserve, Helan Mountains, China. (Alfred J. Andrea)

Despite these problems, once agriculture is established it brings with it a number of benefits. Eventually, assuming proper management techniques are used, farming is far more productive. More people can be supported by less land and resources by agriculture than through hunting and gathering. Agricultural produce can be stored more easily and safely, although it needs to be kept dry and free of pests (such as mice). Agriculture is seasonably predictable and allows for fairly secure long-term planning.

Agriculture seems to also be connected with a sense of ownership. Although we do not have written records for the earliest agriculturists, agriculture requires a sustained investment of labor and resources into a specific piece of land. Thus, concomitant with that must be some sense of territoriality over that cultivated land. Whether this manifests as community boundaries or private property, agriculture requires a greater proportion of the population to become sedentary. Sedentary settlements typically have much greater amounts of things than temporary sites, since people would not have had to carry their goods with them constantly.

Perhaps the problem with understanding the motivations for early agriculture is that the question is incorrect. And since the practice of agriculture has varied so significantly worldwide, it is next to impossible to meaningfully generalize about motivations. Rather than thinking of the switch from hunting and gathering to farming as a conscious choice, it may be better to think of it as a gradual outcome of the interaction between humans and their environment. Agriculture reflects a high degree of human manipulation of the environment. Whereas hunters and gatherers affect their environment by taking from it, agriculturalists actually manipulate their environment by altering the land,

planting crops, and managing herds. Thus, in many cases the development of agriculture should not be understood as a rapid shift but rather as a gradual process in which people took a more active role in influencing the reproductive success of their food sources.

Archaeologically, this process of an increasing manipulation of natural food sources is well documented throughout the world. The earliest evidence comes from the Levant (modern Israel, Syria, and Turkey), where cereal agriculture and animal domestication emerged around the same time as the warming trends of the Holocene epoch began (ca. 12,000 years ago). Prior to this in what archaeologists refer to as the Kebaran period (ca. 18,000–11,000 BCE), wild animals made up a significant proportion of the daily diet. However, some wild cereal crops were also consumed, as is evidenced indirectly through stone slabs, mortars, and other grinding equipment used to process cereals plants. Cereals (such as wheat) have an indigestible husk that needs to be removed before the plant can be consumed. This can be done through boiling (in which the cereal plants are made into a porridge-like substance) or by grinding (in which the plants are transformed into flour). Also present at Kebaran sites are tools for harvesting cereal crops such as stone sickles coated with a silica sheen (the residue from harvesting cereals) still apparent thousands of years later.

Over the course of the next archaeological period, known to modern scholars as the Natufian period (ca. 11,000–9300 CE), the Holocene warming began, and numerous changes to subsistence practices are identifiable. Throughout the course of the Natufian period, there was an increase in the proportion of material culture related to cereal production: more grinding tools are present, and there are more sickles and plaster-lined storage pits for stockpiling grains. Archaeologists have also been able to recover seeds that were carbonized in ancient hearths. Through the analysis of these seeds, it is clear that over the course of the Natufian period people gradually became more reliant on domesticated species of plants.

The main difference between wild and domesticated plants is whether or not the plant can successfully reproduce without human intervention. Wild cereals have a brittle central axis (called a rachis) that breaks easily, scattering seeds. The seeds can be scattered readily by blowing winds, by the movement of animals, or by any number of other natural processes. However, plants with a brittle rachis are difficult to harvest, so those individual plants with a stronger rachis were more successfully harvested. As these plants with a stronger rachis were harvested and the seeds were sown, humans began culturally selecting those traits that were preferable for farming. By the end of the Natufian period, this process, amplified by the natural hybridization of these plants with wild grasses, created domesticated species that were well suited to farming but could not readily reproduce through fully natural processes.

Rather than thinking of the switch from hunting and gathering to farming as a conscious choice, it may be better to think of it as a gradual outcome of the interaction between humans and their environment.

Whereas the difference between wild and domesticated plants can be identified with relative ease archaeologically, it can be a bit more difficult to differentiate between wild and domesticated animals. Some scholars suggest that this dichotomy is often overemphasized in thinking about agricultural origins, and this is no doubt true. However, there are many archaeological instances where it is readily apparent that there was a difference in domesticated animals. As with plants, the key difference between wild and domesticated animals is the role that humans play in the reproductive activities of the animals (i.e., selective breeding). Until genetic manipulation became possible in the mid-twentieth century CE, domesticated animals were generally smaller than wild animals. Sometimes biological features were purposefully bred in animals, such as with domesticated sheep that tend to produce wool that is more amenable to textile production. Zooarchaeologists (archaeologists who specialize in the study of ancient animal bones) can sometimes identify these biological features directly in the remains of the animal bones. More often, though, evidence for animal domestication is indirect. Zooarchaeologists can identify patterns in the age and sex of the animal through remaining bones. By quantifying this data, they can determine whether the group of animals had a natural mortality rate (that is to say, they lived as a wild herd) or if the mortality rate reflects herding practices (since humans make selections on which animals to kill based on practices that will ensure the flock's or herd's long-term growth). Likewise, large groups of animal bones within a human settlement suggest that the animals were domesticated (since it would be quite unusual for a herd of wild horses to live within the confines of a city). Archaeological remains of tools related to animal use further indicate the domestication of animals; yokes and saddles would not be of much use on wild animals.

The transition from wild to domesticated reflects a process of what economic historians refer to as intensification. Agricultural intensification occurs when a society devotes a high proportion of labor and resources into agricultural production and, concomitantly, relies on agricultural production for a large proportion of its dietary needs. Intensification does not always occur when a society develops agriculture, especially when farming has been introduced from elsewhere. However, given the high degree of labor and land needed for agriculture and its potentially high yields, intensification is typical in locations where agriculture develops locally.

Arguably the most readily identifiable evidence of agricultural intensification is the development of complex irrigation systems. Scholars used to believe that only highly centralized governments were able to manage large-scale irrigation schemes. Archaeological investigations have shown that this is not the case; often intensive irrigation schemes actually predate the emergence of centralized states (such as in

Scholars used to believe that only highly centralized governments were able to manage large-scale irrigation schemes. Archaeological investigations have shown that this is not the case; often intensive irrigation schemes actually predate the emergence of centralized states (such as in Egypt, Mesopotamia, India, and China).

Egypt, Mesopotamia, India, and China). However, creating and maintaining irrigation systems requires much labor, planning, and maintenance. Water is absolutely fundamental to agriculture, and local communities must devote significant resources to ensuring that these needs are met. This can involve dramatic changes to the landscape. Irrigation in ancient Mesopotamia involved the construction of numerous small canals to bring the water of the Euphrates to the southern floodplains. These same canals also brought with them tremendous amounts of salt, disastrous to long-term field health, and so the maintenance of the canals and the management of desalinization of fields were essential for avoiding the collapse of the agricultural economy.

Intensive agriculture seems to be related to the growth of cities, although the exact relationship is heavily debated by scholars and seems to vary from location to location. In the Near East, for example, agriculture spreads along with the rise of cities in what V. Gordon Childe referred to as “the Neolithic Revolution.” Agriculture supports urban environments since it allows vastly larger populations to live in much closer proximity. However, identifying which comes first, cities or farms, leads scholars into a type of chicken-or-egg argument that has yet to be resolved. Regardless of which came first, agricultural production is fundamental to urban life, even if it is geographically divorced from it.

Key to agricultural production is that farmers produce a surplus, that is to say, they produce more food than they themselves can consume. This then frees up other members of a society to engage in other occupations besides food production. The emergence of occupations not related to food production is part of a process that archaeologists and anthropologists refer to as the development of complex societies. By referring to societies as being complex, anthropologists do not mean to imply a value judgment. Rather, complexity refers to how intertwined the socioeconomic practices of individual members of a society are. In a less complex society, individual members (or more likely households) produce most of what they themselves consume. In more complex societies, individuals perform one particular type of specialized labor and exchange that labor (or the fruits of that labor) for other goods and services. From this perspective, farming can be understood as facilitating the variety of specialized work that is performed in a society that has access to agricultural production.

Understanding the spread of agriculture is less problematic than understanding the motivations for initiating agricultural production. Once agriculture is well established in a region, it can be highly appealing for nearby locations or can facilitate the colonization of marginal areas. In Mesoamerica, for example, maize cultivation seems to have spread quite rapidly. Although the spread of farming in Mesoamerica is a heavily debated subject, most will agree that by about 4000 BCE maize domestication had occurred in the Oaxaca Valley of Mexico and that by 2000 BCE it had spread throughout Mesoamerica. Other domesticated crops were not initially as successful in this region (although the evidence may be somewhat obscured by the nature of archaeological preservation in the rain forests of Mexico). Maize, however, grew so well and had such a high return on its labor investment that it quickly replaced other forms

of subsistence practices as it was introduced to various locations. As maize domestication became fundamental to Mesoamerican society, the growth of other crops that required more intensive labor eventually followed.

Scholars used to believe that agriculture emerged in a few select locations and then spread throughout the world. Over the past 50 years this view has been challenged, and it has been shown that the development of agriculture varied considerably worldwide. However, there are numerous instances where the spread of farming is indicative of cross-cultural contacts. For example, wheat production in northern China seems to have spread from the Near East along routes that later became known as the Silk Roads. Despite these instances, given the varieties of world ecosystems, the emergence of agriculture was a complex and multifaceted process that defies easy generalizations.

Urbanization appeared rather late in human history but has been transformative. The shift of populations into cities set into motion most of the trends we consider hallmarks of modernity, such as nationalism, imperialism, industrialization, globalization and, in fact, large-scale political structures, such as totalitarianism or democracy.

—Carolyn Neel

Urbanization

Howard Spodek

About 5,300 years ago, people in Mesopotamia and in the Nile Valley created the first human settlements that were large enough in area and population and complex enough in social and economic patterns to be considered cities. These few small urban settlements ushered in a new era in world history. By 2006, United Nations (UN) demographers announced that half of the world's population were living in cities.

Early Urbanization: Cradles of Religious/Political Civilizations

The transformation to an urban world was most clearly registered in the physical construction of cities, with their impressive buildings and crowds of inhabitants, but other equally significant, though less tangible, developments also contributed to this revolution. Cities were nodes in the regional networks of exchange of goods and culture, and they encouraged the production of sophisticated arts, the specialization of labor, and the elaboration of a social hierarchy.

Most significantly, cities signaled the emergence of a state organization for guiding and administering the city and its surrounding area. The new state, usually headquartered in the new city, provided leadership, organization, and official control of armed power. The state governed the people of the city, sometimes with their consent but often without it. The state helped to create and enforce the conditions of inequality that emerged among the people of the new cities. In all these characteristics, the ancient city reminds us of our own.

Unlike modern cities, however, almost all early cities were relatively small. Until the Industrial Revolution in the late nineteenth century, a few thousand people concentrated in 100 acres might have been considered a city, for cities held only a tiny percentage of the total population of any region. The largest city contained perhaps 100,000 people in 8 square miles.

Most experts agree that innovative primary urbanization, not borrowed or imposed from outside, appeared independently in seven different places: five river valleys in the Eastern Hemisphere—Mesopotamia, the Nile, the Indus, the Huang He (Yellow River), and the Niger—and, in the Western Hemisphere, in Mexico and in the Andes mountains. The

birth of primary urbanization took place in these seven locations at very different times, with Mesopotamia the oldest at about 3300 BCE, the Nile about the same time, and the Niger, the most recent, at only about 400 CE.

As the cities grew the shrines grew with them, providing a more profound meaning to the lives of their inhabitants by linking their mundane existence to transcendent and powerful supernatural forces.

Many of these early cities were dedicated to gods and were built on the foundations of existing shrine centers. As the cities grew the shrines grew with them, providing a more profound meaning to the lives of their inhabitants by linking their mundane existence to transcendent and powerful supernatural forces.

Even today we can trace on the surface of the earth the 5,300-year-old designs of some of the first cities and the irrigation systems that supported them. Remnants of walls and fragments of monuments of these first cities still rise at their sites. From under the surface, archaeologists salvage artifacts: bricks; pottery; tools of wood, bone, stone, and metal; jewelry; musical instruments; and skeletons of citizens and slaves. The technology of the early cities also included new means of transportation, and we find the remains of wheeled vehicles and of sailboats. The earliest city dwellers advanced their skills in metallurgy, and products of their craftsmanship in copper, tin, and their alloys abound in the archaeological excavations.

But cities are more than bricks and mortar, metal and artifacts. They require institutions for their larger scale of organization and administration. As societies and economies became more complex, new class hierarchies emerged. Professional administrators, skilled artisans, long-distance traders, local merchants, and priests and kings enriched the diversity and sophistication of the growing cities. External relations with other cities required skilled negotiations, and a diplomatic corps emerged. Armies mobilized for defense and attack. In short, with the growth of the city the early state was also born, with its specialized organization, centralized rule, and powerful armies. To keep track of business transactions and administrative orders, the proclamations of rulers and the rituals of priests, the legends of gods and the histories of the city, new methods of record keeping were developed. At first these were tokens, pictures, seals, personalized markings, and, in the Andes, *quipu*, knots made in special lengths of string. By about 3300 BCE in Sumer, today's southern Iraq, the world's first system of writing evolved. This was one of the most revolutionary inventions in human history. The prestigious occupation of scribe was born, and schoolteachers soon followed.

Cities were the crucible in which civilizations were created and sculpted. The earliest cities held central importance in the religious, political, economic, and social life of their societies. So did later larger and more globally significant cities all throughout the world. For example, Jerusalem and Mecca, neither of them particularly large or geographically central in terms of trade and economics, had and have world significance for millions of people because of their religious centrality. The cultural creativity of Athens in the arts, literature, theater, and government and social organization, at its peak during about 600–400 BCE,

remains influential even today. Rome was a center of empire, beginning about 350 BCE, and later of Christianity. As the Roman empire grew ever larger, Emperor Constantine dedicated Constantinople in 330 to serve as the administrative capital of the eastern regions of the empire. The new eastern capital also served as the headquarters of one of the regional divisions of the Eastern Orthodox Christian Church, and thanks to its location at the point of contact between Europe and Asia, it was also an important port on the trans-Asian silk routes. Baghdad, similarly, was purpose-built in 762 CE as the imperial capital of the Abbasid dynasty and of its caliph, the secular and religious leader of the global Islamic community. In China, Xian, under various names, frequently served also as a capital of the Chinese empire from as early as the Zhou dynasty, about 1100 BCE. Trade along the silk routes also enriched the city, which was one of the easternmost points along that trade network. In the Western Hemisphere, Teotihuacan, about 25 miles northeast of today's Mexico City, also served as a center of empire and of religious worship for central Mexico and Mesoamerica, reaching its zenith, with about 200,000 inhabitants, during about 150–450 CE. Its influence continued under the Maya and other Central American nations. Under various names, Delhi was rebuilt repeatedly from the sixth century BCE, often serving as a capital city for the rulers of northern India. The Mughal ruler Shah Jahan rebuilt it in the seventeenth century as his capital and named it for himself, Shahjahanabad, in large part because of its historical aura. In the early twentieth century, the British rulers of India, wishing to retain the aura without living too close to Indians, relocated the capital of their own imperial enterprise in India to New Delhi, a new city built adjacent to but separate from old Delhi.

These capital cities provided urban designs and architecture that served as models in form and function to the smaller, less prominent cities in their orbit. Their street patterns, political capitols, religious shrines, business offices, and port facilities became templates for others to copy. So, for example, the walls and towers of Xian appeared throughout the cities of China. The aqueducts, roads, and theaters of Rome were replicated throughout the empire. And the raised ritual platforms of Teotihuacan were models adopted throughout Mesoamerica. These distinctive patterns did not always originate in the capital city, but once the capital chose to adopt them, they were copied by others within their cultural and political sphere. (Compare the state capitols throughout the United States, which copy the national Capitol building in Washington, D.C.) Cities everywhere began to tear down their defensive walls after the invention and deployment of cannon rendered them obsolete beginning in the fourteenth century.

Industrious Cities of Trade

Although trade had always been an important component of urban life, traders were usually subordinated to the greater power of political and religious leaders. Beginning about the twelfth century in western Europe, however, traders began to establish their own power bases that

Beginning about the twelfth century in western Europe, however, traders began to establish their own power bases that could rival and even surpass those of religious and political leaders.

could rival and even surpass those of religious and political leaders. In a region of the world beset by warfare among competitive states, the financial resources of the businessmen gave them leverage against rulers seeking support for their armies. Merchant guilds and associations, such as the Hanseatic League of traders in the ports of northern Europe, consolidated that leverage.

In other port cities, like Venice and Genoa in Italy and Bruges and, later, Antwerp in Belgium, where long-distance trade combined with extensive hand manufacturing, merchants dominated. In a city like London, a business ethic devoted to profit suffused public life, attracting men on the make, immigrants seeking their fortune, and those simply trying to survive when agricultural land and work were not adequate to support increasing populations.

Sometimes, as in the enclosure movement in England beginning in the thirteenth century and gaining momentum from the fifteenth century, landed gentry manipulated rural property laws to drive poorer farmers off the land and into the cities. Their double motive was to secure more land for the already landed and to drive potential workers into the labor-hungry growing cities.

Within the cities, open conflict between owners and workers, which Marxists would later label class struggle, broke out. In the fourteenth century, such class antagonisms multiplied. Impoverished workers, suffering also from plagues, wars, and bad harvests, confronted wealthy traders and industrialists. Workers were forbidden to strike and in some towns even to assemble. Nevertheless, class unrest continued to grow. In Florence, Italy, where hundreds of workshops provided work for almost one-third of the city's 100,000 residents, in 1345, 10 wool-carders were hanged for organizing workers. Nevertheless, the productivity and profitability of the trading cities were so obvious that a ruler like Peter the Great in Russia (r. 1682–1725) built a new city, St. Petersburg, to serve as an international warm-water port (open year-round) for his country. As a dictator, Peter simply suppressed revolt when he felt it necessary.

By the eighteenth century, London became the most outstanding example in western Europe of a trading port city, capital of a nation and an empire, center for hand manufacture, and home to an enormous population concentration: 200,000 in 1600, 400,000 in 1650, 575,000 by 1700, 675,000 in 1750, and 900,000 in 1800. In eastern Europe until about 1750, Constantinople was bigger, and perhaps more important, as capital of the Ottoman empire, but London grew primarily because of its economic successes. London's growth promoted the creation of a national market, including the necessary transportation and communication facilities; it evoked increasing agricultural productivity to feed the urban population; it developed new sources of raw materials, especially coal, to provide for them; it encouraged the development of new commercial instruments; and its concentration of population had the effect of increasing productivity and purchasing power. As a rule, pre-

industrial urban giants have high rates of death and of immigration, with the influx of immigrants partially masking the high death rates. London was no exception, and this demographic combination kept England's overall rate of population growth relatively low.

Cities and the Industrial Revolution

Modern cities and the Industrial Revolution created each other. The Industrial Revolution, beginning about 1750 in England, found its home in cities. Once the new workshops and factories, reliant upon steam power and, later, on electricity, were situated in the cities, an entirely new urban form was born. Previously only a minority of people, about 5–10 percent of the population, lived in cities. Urbanites were the elites of society: clergy, professionals, businessmen, and artists. The bulk of the population consisted of farmers. They lived in the countryside. (In some areas, like China and England, powerful elites also lived in the countryside on their estates; elsewhere, as in Italy and Belgium, even landed aristocrats tended to build their homes in cities.) The growth of cities to contain, by 2006, more than half of the world's population is a direct result of the Industrial Revolution.

This modern Industrial Revolution began with simple new machinery and minor changes in the organization of the workplace. It began with mechanization in textiles and continued with the invention of the steam engine and the advances that it made possible in productivity, transportation, and communication. These initial innovations in the late eighteenth and early nineteenth centuries were only the first steps. Between 1860 and the outbreak of World War I in 1914 new technological advances in steel, chemicals, and electricity introduced the so-called second industrial revolution. Ultimately, this ongoing process of industrial revolution multiplied the profits of the business classes and increased their power in government and public life. It broadened and deepened in its scope until it affected humanity globally, transforming the locations of our workplaces and homes, the size and composition of our families and the quality and quantity of the time we spend with them, the educational systems we create, the wars we fight, and the relationships among nations. As a global process, the Industrial Revolution restructured the procurement of raw materials in the fields, forests, and mines of the world, the location of manufacture, and the range of international marketplaces in which new products might be sold. The Industrial Revolution created an entirely new form of urbanization.

The steam engine, which could be constructed anywhere, made the location of industries more flexible. Factories sprang up near port facilities; at inland transportation hubs; in the heart of raw materials resource centers, such as the Midlands of England, Silesia in central Europe, Hubei Province in China, and Bihar in India; and near large concentrations of consumers, such as the great cities of Paris, London, Buenos Aires, and São Paulo. New industrial metropolises dotted the map.

Immigrants streamed into the new cities for jobs, as the balance between urban and rural populations tilted continuously toward the city.

Farmers, pushed off the land by overcrowding and by manipulation of land ownership and tenure laws, became factory workers, and so did the children of artisans. All found the new industrial city shocking. As they exchanged the lifestyles of the farm and the rhythms of nature for regimes of routinization, standardization, and regulation by the clock,

As they exchanged the lifestyles of the farm and the rhythms of nature for regimes of routinization, standardization, and regulation by the clock, they discovered that the skills they had previously mastered were of little use.

they discovered that the skills they had previously mastered were of little use. At the same time, new opportunities beckoned: cultural, educational, recreational, social, and, most important, economic.

In the early years of the Industrial Revolution, conditions of labor and of public health were abysmal. In the middle of the nineteenth century revolution seemed possible, as the urban-industrial working classes felt themselves crushed by the greed

and self-satisfaction of rising industrialists. Socialist and communist movements formed to recruit these workers. Karl Marx and Friedrich Engels, for example, wrote their classic *Communist Manifesto*, calling for a workers revolution—"workers of the world unite; you have nothing to lose but your chains"—in 1848. They went beyond the usual accusations of owners and managers exploiting workers through low pay, long hours, and awful working conditions. They condemned the filth and squalor and the high rates of mortality and morbidity of workers' neighborhoods. Surprisingly, many of their condemnations of the urban-industrial city pointed out the suffering of owners as well as workers: the separation of the city from the countryside, which left everyone alienated from nature (and degraded nature at the same time); the alienation of many owners and managers as well as workers from their work, as they became insignificant cogs in great systems of production; the rapidity of change, which left people feeling adrift; the evolution of a family structure, which ended the allegedly greater egalitarianism of the rural family; and the endless competition, which drove workers as well as owners to serve the unceasing economic demands of the capitalist system. All of these were products of capitalism and symptoms of the cities that the Industrial Revolution created.

In their call for revolution and because of their belief that it was inevitable, however, Marx and Engels failed to account for three developments in most of the urbanized industrialized world. First, politicians in search of votes in newly democratizing countries proved responsive to industrial workers. They legislated minimum wages, maximum hours, safer working conditions, and greater political representation for urbanites, in contrast to rural dwellers. These led to improvements in urban cleanliness, public health, and provision of urban services. Second, workers formed labor unions that won important benefits. Finally, workers created social networks that frequently brought them an important sense of belonging, of social solidarity, and of joy despite their difficult living conditions. The revolution against the capitalist industrial system did not occur, or at least it did not occur in the most industrialized and urbanized countries. On the contrary, revolutions occurred in Russia

(1917) and China (1949), countries low on the scale of urbanization and industrialization.

Industrialization fueled city growth. By the turn of the twentieth century, England and Wales, at 62 percent urban, were by far the most industrialized and the most urbanized regions on earth. The next closest were Australia, at 42 percent, and various parts of Germany, at about 30 percent. In general, the largest cities were growing fastest. London, the world's largest city in 1890, had 4.2 million people; New York, the second largest, had 2.7 million. The least industrialized countries were the least urbanized, below 10 percent. Conditions of urban life were improving, including increasing levels of longevity and personal comfort. New inventions such as electric lights, the telephone, and the phonograph improved the quality of life. On the other side of the ledger, although death rates in the city had been declining steadily, urban death rates remained higher than rural ones in most countries. In one of the worst examples, during the decade 1880–1890 when the expected length of life at birth for all of England and Wales was 47 years, in Manchester, one of the greatest centers of the early Industrial Revolution, it was 29 years.

The new industrial cities transformed family relations. Factory work drove a wedge between the home and the workplace. Wives who had been accustomed to working alongside their husbands on the farm or in the shop now found that the major source of employment was away from home. Most middle-class women spent a great deal of time caring for their families and homes, and the new urban domesticity increased their level of security and comfort. Life expectancy, a basic index of well-being, rose rapidly for women in Britain, slightly more than for men. It increased from 44 years in 1890 to 52 years in 1910 and to 60 years in 1920. Living standards began to rise and generally continued to rise into the twentieth century. New systems of ventilation, heating, lighting, indoor plumbing, and running hot and cold water contributed to making life easier for those who could afford them, although these facilities often did not reach working-class neighborhoods.

Urban conditions made children less of an economic benefit, as they had been on family farms, and more of an economic burden. Family planning increased. Childbearing became less frequent, freer from infection thanks to antisepsis, less painful with the use of anesthesia, and safer with the professionalization of medicine. The presence of children in the home also decreased as free compulsory education, beginning as early as the 1830s and 1840s, began to take them to school for several hours each day.

With more time freed from traditional domestic responsibilities, some women began to enter into the array of white-collar jobs that were opening. The most respectable jobs provided satisfying work that also fit the culturally approved role of women as caregivers and nurturers: teaching in the new school systems and nursing in the new hospitals. Other women worked as sales personnel in the new department

stores (where they also shopped) and as secretaries and clerks in the new offices, although in the nineteenth century these were primarily male occupations. A very few went into the professions: medicine, law, journalism, and business.

The 15–20 percent of adult females who had to work as principal breadwinners for themselves and their families confronted more basic problems of earning a living. The value placed on domesticity as the proper role for females and the concomitant view that men should earn a “family wage” adequate to support their wives and children, but that women needed only supplementary income (“pin money”) made the plight of the working woman doubly difficult. These women, often immigrants, desperately poor, and without male support, were no longer seen, as the first industrial women workers had been, as proud and independent but instead as unfortunate objects of sympathy and pity. They found jobs where they could. Domestic service was most common, employing two to three times as many women as industry even in industrialized countries. On the margins of society, other women earned a living through prostitution. In the second half of the nineteenth century, censuses in the largest west European cities, London and Paris, routinely reported tens of thousands of prostitutes walking the streets, serving in brothels, or, occasionally, employed in more comfortable settings by more prosperous clients.

Cities of Empire and of Finance Capital

As Europeans began to master new technologies, first of business and then of industry, they extended their search for markets—buying raw materials, selling finished products—around the globe. As early as the fifteenth and sixteenth centuries, the Europeans established the pattern of planting their new colonial cities on seacoasts so that they could be supplied easily by ship from the mother country. The newer colonial cities of the age of the Industrial Revolution continued this pattern, for example, from west to east: Lima, Buenos Aires, Rio de Janeiro, Dakar, Lagos, Cape Town, Karachi, Bombay, Colombo, Madras, Calcutta, Kuala Lumpur, Singapore, Batavia (Jakarta), Hong Kong, and Manila. Many were built as dual cities. That is, they were built contiguous to already-existing cities, for example, Casablanca, Algiers, Mombasa, and Shanghai’s foreign concessions. Later, in the nineteenth and twentieth centuries, as Europeans penetrated ever deeper into their colonial realms, they built cities in the interior as well: New Delhi, Kandy, Harare (Salisbury), Lusaka, Nairobi, and Kampala. Several of these were also dual cities.

The Spanish had built their cities in the Americas for permanent residence; the new cities in Africa and Asia were normally built for temporary residence by colonial officials and those working with them. They did not buy land and real estate locally. The residences were permanent, but the residents were transients. At the end of their imperial service, these residents would normally return to their home countries.

The colonial city was designed to serve the economic and administrative needs of the colonial power more than those of the indigenous

peoples. The technology was usually European, and the town planning, although modified for the climate and political conditions of the colonial situation, was usually derived from European models. Railway networks connected port cities to the sources of raw materials and provided means for transporting colonial soldiers to the interior as needed. They did not necessarily connect the indigenous cities to one another. The development of industry, the key to urban growth in western Europe, was sharply limited in the colonial cities. The modern industries that were built in these new cities were mostly, but not entirely, owned and controlled by Europeans. While apologists for the imperial system gave it credit for introducing industrialization where it had previously been unknown, more critical commentators called this a system of dependency in which the colonial powers used their political and military authority to rig the economy—imports, exports, taxes, commercial agriculture, banking, and limited industrialization—for their own benefit, leaving the colonized people dependent upon them.

The dual-city pattern was the norm. The European enclaves were quite distinct from the indigenous city: more spacious (lower density) in overall design, with wide tree-lined roads; grand accommodations for the European administrators and officials who lived there; architecture built to European design, topped off with ornamental touches to acknowledge particular local styles; spacious and impressive offices equipped with modern machinery; and shops with glass show windows and consumer products of fine quality, often imported from Europe. In the larger cities, higher up the administrative ladder and especially in colonial capital cities, the public buildings were often built to monumental scale. Churches, too, dotted the landscape. Great attention was devoted to the cleanliness of the European neighborhoods. The Europeans feared local diseases—and local culture—and did their best to keep them at a distance.

Residence in these enclaves was often restricted to Europeans and people who worked with them. Most local people lived in the indigenous city, which was built to very different specifications, often reflecting quite different resources, social organization, institutional structures, and values. These indigenous cities were comparatively crowded. They were often built within long-standing protective walls, which unfortunately reduced air flow, and had narrow, twisting streets. Neighborhoods were based on local kinship patterns, and there was comparatively little public greenery, although larger homes, which turned blank walls to the street, often had lovely gardens in interior courtyards. Shop fronts were opened fully in the daytime but were completely shuttered at night. Artisans frequently practiced their crafts within their homes or on the street directly in front of them. Streets were crowded with people throughout the day and well into the night, especially after the arrival of electricity and street lighting, and many events that might have been

considered private in the European enclave, such as marriages and funerals, were celebrated publicly, out of doors, in the indigenous sections of town. Public streets were not usually as clean as in the enclaves, and animals often shared the narrow streets with humans, cleaning the streets by eating refuse and soiling the streets by producing refuse. Religious institutions (mosques, temples) were often the most imposing structures in the indigenous city, and small neighborhood religious shrines dotted the urban landscape. Since private resources were often limited, public institutions, such as community baths and bakeries, were often provided throughout the city. In these regions, some 80–90 percent of the population continued to live in rural areas.

The colonial cities, despite their residential segregation, offered—and required—interaction between the colonial rulers and the local colonized people in offices, shops, industries, and schools, although not so much in recreation. The results of this interaction were unpredictable. Not only the social science literature but also biography, autobiography, fiction, drama, and films are filled with the stories of indigenous people and colonial rulers who were transformed in one way or another through their interactions with the diverse residents and the institutions of the European colonial cities, often in quite complex and ambivalent ways.

City Life and Culture

Philosophical and sociological speculations on the nature of the city flourished. In Germany, Max Weber (1864–1920) analyzed the modern industrial city as a new creation. He contrasted, negatively, its free-wheeling life and amorphous institutions against the close-knit guilds and political and religious associations of earlier self-governing European cities, especially medieval cities. Weber concluded that the sprawling industrial city—open to any immigrant who wished to come and embedded within a nation-state that controlled its life and politics—was quite different from the self-contained city of earlier times. Europe, at least, was living in a new era.

Many observers agreed, apprehensively. To them the openness of the new industrial city and the lack of institutional ties among its citizens seemed to be leading to breakdowns of both the social fabric and the individual personality. The division of labor was turning the individual into a specialist concerned only with narrow interests; the sense of personal or community wholeness was lost. And the sheer multitude of people and experiences in the city was also forcing the individual to retreat even further into a small, private niche. The urban dweller, they felt, was evolving into a person swift of intellect to achieve his own needs but lacking concern for and integration with the larger community. On the other hand, sociologist Emile Durkheim believed that the need to find common policies for the city would bring its residents together in what he called “organic solidarity.”

Some observers claimed to see the negative effects of urban individualism as part of a historical process that would ultimately lead to

disaster. Oswald Spengler (1880–1936), a German philosopher of history, declared that the enormous “worldcities” of his day were inevitably destroying the spirit of the folk peoples who had built them. Such attacks on urban life perpetuated the centuries-old cultural struggle between the cosmopolitan city of businessmen and the (perhaps imagined) homogeneous countryside of the common folk. This view of tough and rugged rural people confronting effete and weak urbanites had found expression in the Arab world five centuries earlier in the *Muqaddimah* of Ibn Khaldun of Tunis (1332–1406).

In the United States, with millions of immigrants streaming into its cities in search of industrial jobs, urban diversity was accepted, even valued, and certainly studied. Scholars at the University of Chicago examined their own city, the world’s fastest-growing industrial metropolis of the day, studying neighborhoods as well as the metropolis as a whole. The Chicago

School of Urban Ecology cited the importance of the “central business district,” the downtown area, but also pointed out that most urbanites did not live their lives downtown, as so many previous scholars had implied, but rather in neighborhoods, each of which had its own characteristics. Within these local domains, often characterized by high levels of homogeneity in class, religious affiliation, racial identity, and family size, people’s lives were not so disconnected, isolated, or alienated.

This view of tough and rugged rural people confronting effete and weak urbanites had found expression in the Arab world five centuries earlier in the Muqaddimah of Ibn Khaldun of Tunis (1332–1406).

A Single Global System of Cities

Following World War II, the Cold War had divided the world into the First World of capitalist democracy, the Second World of Communist Party dominance, and the Third World of mostly impoverished colonies. Then, with the fall of the Soviet Union (1989–1991), the entire tripartite division gave way to a more thoroughly integrated global system of cities.

The geographical distribution of cities shifted in an unexpected way. Economic growth and urbanization no longer seemed to be naturally related to one another. Previously cities had mostly arisen in wealthier regions. Their growth seemed to be a product of the pull of urban economic growth and job opportunities. In the late twentieth century, however, cities became characteristic of the poorer regions of the world. They seemed to grow not as producers of new wealth, but rather as the refuge of migrants fleeing an overpopulated countryside with its scarcity of land and jobs. In 1900, cities in the economically developed world held about 163 million people; those in the underdeveloped world held about 97 million people. By 2000, the developed world held 900 million urbanites, the underdeveloped world 2.15 million.

The economic functions of cities also changed dramatically. The large-scale industrial manufacture of commodities, such as steel in Pittsburgh, automobiles in Detroit, and textiles in Mumbai went into decline and even collapse. Service industries became the engines of new urban

growth: the information technology of California's Silicon Valley and India's Bangalore; the film industries of Hollywood and Bollywood; the theme hotels of Las Vegas and the more overtly risqué attractions of Bangkok and Manila; the amusement parks of the Disney empire in the United States, Europe, Tokyo, and Hong Kong; and the tourism of such holiday destinations as Cancun, Rio de Janeiro, Monaco, Cape Town, and Sydney.

So extraordinary were the size, technological transformation, and global integration of twentieth-century cities that many observers viewed this combination as a fourth turning point in world history, equivalent in its impact to each of the three earlier settlement revolutions: the move from nomadic existence to settled village life, the establishment of the first full-fledged cities, and the creation of industrial cities.

To what degree did the global system of cities encourage similarities in the internal systems in cities everywhere? The new technology of the Web and the new political economy of more open borders produced globalization, the linking of cities and regions into global networks for the exchange of information, capital, commodities, and labor. This did not mean that cities were becoming more equal. Some urban

The new technology of the Web and the new political economy of more open borders produced globalization, the linking of cities and regions into global networks for the exchange of information, capital, commodities, and labor.

centers, such as New York, London, and Tokyo, remained dominant and even increased their dominance. At the other extreme, some regions were hardly touched by globalization. Only 13 million (1.7 percent) of sub-Saharan Africa's 765 million inhabitants used the Internet in 2005. By contrast, in the United States, Japan, South Korea, Canada, Australia, and the Netherlands, about 2 of every 3 residents used an Internet connection.

A group of urban scholars, sometimes called the Los Angeles School, claimed that Los Angeles was becoming the model of the emerging global city. They cited, first, the sheer growth of the metropolis. By the end of the twentieth century the Los Angeles metropolitan region held a population of 12 million, spanned a diameter of 120 miles, included 5 counties and 132 incorporated cities, a vast hinterland of individual cities, each with its own personality; it produced a gross annual economic output of nearly \$250 billion. Then they noted the characteristics of Los Angeles that seemed to be spreading universally: the lack of a single geographical center in the metropolis; vast social divisions and inequities among its ethnically diverse residents; the absence of a dominant central business district, of a dominant social and economic group, and of a normative cultural style. The urban agglomeration expanded on the basis of a fast-growing economy with a strong emphasis on consumption. Many sectors of the economy were in "sunrise" industries of growth: the film industry and the fashion industry that surrounded it; high-tech industrialization, much of it based on production for warfare (airplanes, missiles, and electronics); international containerized shipping in this leading port city of America's west coast, its key Pacific Rim harbor; high levels of immigration, both high- and low-skilled, from sev-

eral continents; challenging ecological problems arising from its semi-desert location and its situation in a kind of topographical bowl as well as its reliance on millions of privately owned cars running on endless miles of freeways as the principal means of transportation.

With the Web and email providing inexpensive instantaneous communication everywhere in the world, manufacturers relocated many of their production facilities to poorer areas where wages were lower. The cities of developed regions were shifting out of manufacturing, the segment of the economy that had created their importance, into services.

China was the great exception. It showed continuous growth in urban manufacturing. China instituted four “special economic zones” to stimulate development. The largest, the city and region of Shenzhen, next door to Hong Kong, grew from virtually no population in 1980 to 12 million in 2005. Manufacturing, trade, and services flourished. Directly across the Huangpu River from Shanghai, the Chinese government designated Pudong a “national project” in 1991, also with the status of a special economic zone. By the early years of the twenty-first century, Pudong held some 10,000 financial, commercial, and trade institutions from over 60 countries in over 100 high-rises, among them some of the world’s tallest skyscrapers. China’s urban population rose from 16 percent in 1960 to 19.6 percent in 1980 and then jumped sharply to 35.8 percent in 2000 and 40.5 percent in 2005.

Communist Vietnam adopted similar policies of urban development through state-aided capitalist enterprise. Ho Chi Minh City in the south and Hanoi in the north, cities which had been cut off from the global economy for decades, were now joining it and adopting urban bourgeois consumer styles. (Most national communist parties did not, however, allow political democracy, at least not yet.) The Soviet Union also remained committed to centralized state planning, with an emphasis on manufacture, under a single-party state until 1989–1991, when the country dissolved as a political entity. Russia’s urban population reached 73 percent in 1990 and stabilized at that point. Ethnic diversity in the major cities, especially in Moscow, increased. Immigrants from regions of the former Soviet Union, as well as Turks, Arabs, Chinese, and Vietnamese arrived in search of work. Ethnic competition sometimes erupted into violence.

Russian cities, previously suffering in austerity under communism, began to see new shops open and private businesses flourish, quickly giving the cities more life and color. Advertising proliferated. Business services, a sector of the economy virtually nonexistent under communist rule, expanded to employ almost 10 percent of Moscow’s workforce by 2000. Many of the members of this new class were young, just beginning to master the language, computer, and business skills of their new tasks. Often they had served as Communist Party bureaucrats, had gained experience in administration, and had cultivated the connections to buy the businesses at bargain-basement prices from the state which was now withering away. Their prosperity

inspired envy. Entrepreneurs founded new commercial outlets to attract their disposable income. By 2005, Moscow was estimated to have 33 billionaires, more than any other city in the world, and about 30,000 millionaires.

Migration to the City

Many global megacities, like Los Angeles, had high rates of diverse immigration, fragmented social groups, and tense separations among classes. The huge megacities of the Third World attracted migrants from all parts of their nation and beyond. Abidjan drew from all of the west African Sahel, Mexico City drew from throughout Central America, and Shanghai drew from the entire Yangzi River basin. Oil-rich cities of the Persian Gulf attracted migrants from the surrounding Arabian Sea periphery in Africa and Asia. (Sometimes their growth seemed fragile, as the collapse of the Dubai economy in 2009 suggested.) European cities received immigrants from their former colonies. For example, Paris attracted immigrants from northern and western Africa, while newcomers to London came from India, Pakistan, and the West Indies. Even without imperial connections, millions immigrated especially from Yugoslavia, Turkey, and southern Italy. Millions came from Islamic countries, introducing a new religious element into many European cities. By 2000, 15 percent of Paris's population, 50 percent of the population of Amsterdam, and 15–25 percent of the population of Frankfurt, Stuttgart, and Munich was made up of international migrants.

As in Los Angeles, tensions accompanied the uneasy mixture of diversity and inequality. Violence broke out. Urban riots across India in the 1990s and early 2000s pitted Hindus and Muslims against one another as social upheaval, religious tension, and political grandstanding combined to inflame both spontaneous mobs and organized rioters. Violence among competing criminal gangs also broke out periodically in many cities around the world. Not all urban violence was based on immigrant diversity. In many countries, electoral contests and sports competitions evoked periodic outbursts.

Spatial divisions among classes, ethnic groups, racial groups, and lifestyle groups within the city increased and hardened. Sometimes actual walls were erected between different neighborhoods. In America these were referred to as “gated communities.”

Patterns of social segregation were common. Spatial divisions were increasing whether cities were industrializing or deindustrializing, whether they seemed to be on the leading edge of globalization or excluded from it. Cities were so deeply divided spatially that their residents could live out their daily lives almost completely within geographically self-contained divisions. Residence, work, recreation, and socialization were all available within their quarters of the city. These quarters also tended to house people of similar political beliefs and affiliations.

Reactionary political parties saw benefits in proposing bans on immigration and even the expulsion of immigrants who had already settled. Parties like the National Front of Jacques Le Pen in France and the

Lega Nord in Italy introduced opposition to immigration and immigrants as essential planks in their political platforms. At street level, fights between immigrant and native youths became frequent, sometimes accompanied by assaults on property. In many European cities, youths proclaiming fierce nativism shaved their heads and, as “skinheads,” sought out “foreigners” to attack. Their victims often included residents who had been in place for a generation and more. In England the phenomenon was referred to as “Paki[stani]-bashing.” In France, especially, religious conflict merged with cultural conflict as the Muslim population coming from the former colonies in North and West Africa increased. In 1995 and again in 2005 rioting shook the immigrant, relatively poor suburbs that ringed the outer periphery of Paris and spilled over into other cities in France and even into the Netherlands and Belgium. In Rome, immigrants from countries in southeastern Europe and North Africa were targets of attack. Debates on immigration policy entered into national as well as local politics, as candidates for office proposed diverse economic, cultural, and political recommendations. American cities, too, had ethnic clashes and racial tensions. During the civil rights movement of the 1960s, rioting broke out in many American cities. In 1992, the most destructive urban rioting in the history of the United States erupted in Los Angeles when a court exonerated white police officers who had been captured on videotape beating Rodney King, an African American.

In 1995 and again in 2005 rioting shook the immigrant, relatively poor suburbs that ringed the outer periphery of Paris and spilled over into other cities in France and even into the Netherlands and Belgium.

Urban Slums and Policies

In the poorer countries of Asia, Africa, and South America, urban slums continued to expand in size and population. The UN estimated that 924 million people lived in slums worldwide in 2001, about 32 percent of the global urban population, with higher proportions in the cities of the developing world. Cities and nations experimented with diverse strategies for coping. Until the 1960s, most plans advocated the construction of public housing to accommodate new urban immigrants. The cost, however, was prohibitive. By the 1980s, programs of “sites and services” won favor. Governments would provide slum dwellers with individual plots—usually about 200 to 250 square feet—and basic municipal services of water, sewage, and electricity and then leave it up to the recipients of the plots to construct their own housing with their own resources. Even with this low-cost strategy problems remained. Who would get the plots? How would allocations be made? For the poorest of the slum dwellers, construction and maintenance costs were still expensive. After construction, the owner-builders often sold off their new homes to more middle-class buyers and returned to the slums, preferring the money to the home.

By the 1990s a new strategy of slum upgradation gained acceptance. Governments retrofitted existing slums with water and sewer lines and

electric connections and realigned their street plans. Most important for assuring residents of stability, they sometimes provided deeds or other legal rights to tenure. These interventions improved the physical quality of life of the residents while maintaining the basic social structure and organization of the slum. Tenure, when granted, encouraged residents to invest in the improvement of their properties, secure in their ownership and protected against eviction. In some cities, these structural improvements were supplemented with social, health, and educational services. As governments and nongovernmental organizations (NGOs) gained experience, they created a wide array of partnership programs to work with—rather than for—the slum dwellers.

By the turn of the millennium, differences among the regions of the world were emerging clearly. Cities whose economies were generally improving, as in much of East and Southeast Asia, and those that implemented specific policies to improve the lives of slum dwellers, as in much of Latin America, showed progress. On the other hand, in Africa the proportion of slum dwellers continued to rise rapidly. Everywhere legality of tenure was an issue. Without legal tenure, squatters could maintain their toeholds in the city only through collective organization. Corruption flourished as slum organizers had to negotiate deals with the police and the politicians.

Global Research and Planning

By the early twenty-first century, global urbanization had a new look. Half the world's population lived in urban areas. Metropolises sprawled for miles in all directions. The historic city, with its legally delineated boundaries, became less distinct and less significant as a functional unit. The end of the Cold War and the advent of the World Wide Web broke down international boundaries and allowed cities to enter into a world wide system of cities. In 1976 the UN sponsored the first Conference on Human Settlements, called Habitat I, in Vancouver, Canada. Habitat II followed in Istanbul in 1996 and Habitat III, again in Vancouver, in 2006. The conferences addressed a wide spectrum of concerns, including physical planning, ecology, group relations, women's issues, youth organization, slum improvement, neighborhood planning, and the historic preservation of significant structures from the past. Urban research and study centers, linked to government, to universities, and to NGOs, multiplied around the globe.

Cities were now firmly embedded in regional systems and global networks of communication, trade, and migration. Urban research and urban planning attempted to keep pace. It was easy to argue that the pattern of settlements around the world had indeed entered a fourth stage.

As Dr. Roscoe considers the origins of complex political organizations, as well as their benefits and detriments, many questions arise in a reader's mind. Why do we have governments? What is involved in creating them? Are they really necessary? Do they arise from our desire to live in groups? Would organized states exist if not in opposition to each other? What would happen if there were only one government? As we think through these issues with Dr. Roscoe, we realize that simple or simplistic theories may comfort us, but they provide no dependable answers.

—Carolyn Neel

The Evolution of Complex Political Organizations

Paul Roscoe

Introduction

By the evolution of complex political organization, scholars generally mean the recent and sudden elaboration of the scale and complexity of human political organization. For most of our time on earth, humans have been a hunter-gatherer species, existing in communities with minimal divisions of labor, social stratification, and political centralization. In just the last few thousand years, however, this situation has been transformed, creating a world in which a tiny minority of the species has come to enjoy colossal wealth and enormous power over the rest and in which professions as rarified as professors and lifestyle counselors now flourish. Complex political organization works to both the benefit and detriment of humanity. On the one hand, it supports technological and organizational infrastructures capable of eradicating some diseases from the planet and of ameliorating the impact of natural catastrophes that once would have wiped out whole populations.

In the not-too-distant future, we shall even have the capacity to detect and deflect asteroids, safeguarding earth from the kinds of collisions that, in the past, have extinguished multiple species. On the other hand, complex political organization and the technologies that it supports and that support it have enabled damage and destruction on a scale unimaginable just a couple of centuries ago. In just the last century, these developments have enabled the industrialized slaughter of some 9 million people in the First World War;¹ the extermination under the Third Reich of around 6 million Jews, a quarter to half a million Gypsies, 200,000 to 250,000 mentally and physically handicapped people, and several thousand homosexuals and Jehovah's Witnesses, not to mention the murder of millions of civilians under Nazi occupation² and the deaths by execution or forced labor of at least 3 million Soviets during the Great Terror of 1937–1938 (a total of 20 million or more people perished over the entire course of Stalin's rule).³ Since then, complex political organizations have placed in our hands arsenals of thermo-nuclear weapons capable of eradicating most species and all human life

If we are to survive on this planet and improve the lot of humanity, we need to understand the processes that gave rise to complex political organization and propelled its development.

from the face of the planet. And in the future, their likely seed will include the introduction of genetically engineered bioweapons to which we have no immunity and alterations to the earth's climate that at a minimum will alter the distribution of vegetation belts and raise sea levels and, in darker scenarios, might trigger a new ice age. If we are to survive on this planet and improve the lot of humanity, we need to understand the processes that gave rise to complex political organization and propelled its development. This essay begins with a brief account of how these organizations have developed in prehistory and history and then reviews some basic ideas about the workings of political evolution. The conclusion briefly reflects on the future of complex political organization.

The Emergence and Development of Complex Political Organization

Political organization and political evolution mean different things to different people, but commonly the term “political organization” refers to the level of development (or elaboration) of a society’s division of labor, social stratification, and political centralization, while the term “political evolution” refers to the processes that propel this development. The term “division of labor” refers to the level of a society’s occupational specialization: the degree to which different occupations (e.g., farming, fishing, and pottery) are assigned to different people as opposed to being responsibilities expected of all. The division of labor is said to be minimal, for example, if everyone—or at least every family—undertakes its own farming, fishing, pottery, and the like; at the other end of the spectrum, tasks become lifelong occupations (farmers, fisherfolk, potters), and the division of labor is said to be developed or complex. The term “social stratification” refers to the degree to which access to important resources is restricted. In unstratified communities, everyone has the same access to resources; in highly stratified communities, access to economic resources such as land and wealth, to political and military resources like councils and weaponry, and to social resources such as membership in country clubs or entry to finishing schools is restricted to an elite. Finally, the term “political centralization” refers to the degree to which power—the capacity to secure outcomes through the agency of others—is centralized in the hands of a few. In egalitarian societies, disparities in power are minimal: although adults invariably are able to direct the behavior of children, they have negligible ability to influence the behavior of other adults. In politically centralized societies, by contrast, a minority of the population—be it a noble or royal court, a parliament, or a capital—may have enormous power over others.

For most of hominin and human history, political organization has been small-scale and political evolution minimal. The hominin lineage split from a common chimpanzee-hominin ancestor some 5 million to

10 million years ago, and over the ensuing millennia it developed numerous branches, most of which had become extinct by the time modern humans, *Homo sapiens sapiens*, emerged some 50,000 to 150,000 years ago. Like their predecessors, early modern humans lived a hunter-gatherer life. Archaeological evidence and inference from ethnographic fieldwork among historically known hunter-gatherer populations suggest that they were mobile, roaming the landscape in small scattered bands of perhaps 20 to 50 kinsfolk. The division of labor in these groups was extremely limited, principally following lines of age and sex. In addition to their work in bearing and raising children, women probably gathered small game and much of the plant food in the diet, while men hunted larger game and, where necessary, defended the band from human and animal predators. Stratification was minimal, communities were egalitarian, and gender relations were likely characterized by an unusual level of equality.

This picture may have begun to change when humans first took up fishing on a large scale. Evidence from historically known forager communities reveals that a subsistence regime of plant gathering coupled with heavy reliance on aquatic resources generally correlates with higher population densities and larger and more permanent settlements than are observed in communities that combine gathering with hunting. In these fisher-forager communities, we also witness the emergence of political leaders, who have a limited ability to influence the behavior of others and a slightly greater access to spouses and material resources. There is considerable uncertainty over when humans first developed a heavy dependence on fishing: opinions vary from 40,000 or more years ago to fewer than 8,000 or so years ago. If fisher-forager communities predated the beginning of the Holocene, around 12,000 years before the present (BP), however, it is possible that the first complex political organizations on earth emerged in fishing societies. Whatever the case, complex political organization failed to develop further until humans began to purposefully manipulate their environment by domesticating animals and, more importantly, cultivating the soil. With the emergence of agriculture some 10,000 years ago, human populations now had the capacity to intensify food production beyond the limits imposed by the natural environment. As a result, over the next few thousand years communities in several parts of the world became denser and more sedentary, and with these developments political organizations began to grow in scale and complexity.

Whether the first politically complex communities emerged among fisher-foragers tens of thousands of years ago or among cultivators within the last 7,000 to 10,000 years, early complex political organization likely resembled that of the political communities documented in contact-era New Guinea. At the beginning of the twentieth century, New Guinea was the so-called Last Unknown, a great continental island that was home to some 2 million people, most of them cultivators. New Guinea political systems, it was soon discovered, were very similar to those in egalitarian hunter-gatherer bands, but they differed in two crucial regards. First, they boasted either great-men or big-men leaders. In great-men societies, some men had achieved a level of eminence for

The second difference between the cultivating societies of New Guinea and the egalitarian bands of early foragers was the emergence in the former of male political domination: although women could exert some influence through informal means, they were commonly excluded from formal participation in political affairs.

their prowess as warriors, hunters, and/or religious specialists. In big-men societies, some men had managed in addition to accumulate a limited degree of power. They were able to sway community opinion and, to a degree, influence the behavior of others, and they competed to display this power by sponsoring large feasts, distributing substantial amounts of valuables (notably shells and pigs), acquiring multiple wives, and occasionally sponsoring the construction of spirit houses. The second difference between the cultivating societies of New Guinea and the egalitarian bands of early foragers was the emergence in the former of male political domination: although women could exert some influence through informal means, they were commonly excluded from formal participation in political affairs.

The defining feature of the big man—and even more so the great man—was the limited reach and temporary nature of his power. Big men seldom held sway over more than a few hundred people. Big men could influence the behavior of others but rarely could they compel it. And they did not inherit whatever power they enjoyed but rather created it themselves. A big man had to build his power base from nothing, and when he became too old to maintain it, it disintegrated; he was unable to pass it on to a descendant. Sometime during the Early to Middle Holocene, however, this situation changed when a new form of political organization and leadership emerged: the chiefdom, centered on a chief. The levels of power enjoyed by chiefs varied markedly. Some commanded hardly more power—perhaps even less—than did a big man, but others enjoyed enormous power. The three high chiefs of Tongatapu in the Tongan archipelago, for example, ruled over a population of some 15,000 people and were able to appropriate the belongings and labor of the lower classes at their pleasure. Both the necessities and the luxuries of life were supplied to the chiefs by the people, and even “inferior” chiefs could physically abuse and even murder their followers with impunity. William Ellis, surgeon’s second mate on Captain Cook’s third voyage to the Pacific, was ashore on Anamooka in the Tongan archipelago when a chief ordered a market crowd to disperse. When the people proved too slow for the chief’s liking, he took up a club and began laying about him. “One man was knocked down and when taken away was to all appearance dead. The agee [chief] took no notice of it, and walked away as unconcerned as if nothing had happened.”⁴

Typically, chiefs had considerably more power than big men, but what distinguished them from the latter was that they inherited power by virtue of their birth. Inherited leadership is not restricted to chiefdoms: it existed in many New Guinea societies, where clans commonly were led by headmen who inherited their position through primogeniture (i.e., as the first-born son). But these were ceremonial rather than political positions, the difference between being the queen of the United

Engraving titled "The Natche, a ceremony in honor of the King's son, in Tongataboo," from Captain James Cook's Voyage to the Pacific Ocean, 1785. (Library of Congress)

Kingdom rather than its prime minister. Headmen might be official war leaders and peacemakers, ceremonial orators and officiants at wealth distributions and ceremonies, but they were not necessarily big men, nor were big men necessarily headmen. Indeed, if a headman had power, it was by virtue not of his office but of his political abilities in creating it. In a chiefdom, by contrast, chiefdomship conferred power, often very considerable power, and access to this power was restricted to the members of a noble family.

The emergence of inherited power is commonly accompanied by a further important political development: the institutionalization of stratification. In egalitarian hunter-gatherer bands, stratification was all but nonexistent. Adults enjoyed greater access to important resources than did juveniles, of course, but there was little or no stratification by gender and none among people of the same age and sex. In great-men and big-men communities, leaders might enjoy a few more privileges than their fellows: multiple wives, marriage to powerful allies, and perhaps a slightly greater control of land and important trade routes. Some of the most powerful big men in New Guinea even had small retinues of bachelors and war refugees in their households who provided them with labor in return for economic support and protection. But this stratification, like the big man's power, was as ephemeral as it was modest, his wealth and privileges usually dissolving at his death. In a chiefdom, by contrast, a chief's differential access to resources survived his or her death, passing to an heir as an integral component of the office of chief. The Polynesian island of Tahiti, for example, was divided at contact into 11 chiefdoms ranging in size from around 1,000 to 15,000 people, each ruled by a chief who could claim descent from a long genealogical line of royalty. As part of their office, the most powerful of these chiefs inherited by right of birth large landed estates (one of which included a nearby island "vacation resort"), elaborate houses and clothes, and courts staffed with priests, political advisers, entertainers, cooks, domestic assistants, and a retinue of burly young men whose job it was to carry the lord on their shoulders on state visits to other parts of the island. To subsidize these lavish lifestyles, followers were obliged to pay tribute in

the form of breadfruit, pigs, fish, tortoise meat, boats, mats, bark cloth, war decorations, and the like; to supply labor to construct their chief's houses, canoes, and irrigation systems; and to serve in his armies when it suited his ambitions to wage war on a rival.⁵

Some 5,000 years ago, the first state-level political organizations appeared on earth. The difference between an advanced chiefdom and an early state is more arbitrary than real, but a state is commonly defined as an organization that possesses a centralized bureaucracy and claims a monopoly on the exercise of physical violence within its borders. Whereas the Tahitian chief might have a cadre of advisers to assist him in collecting tribute and levying labor for his projects, a state has a formal body of officials whose job it is to keep track of and collect taxes, settle disputes, organize state projects, raise militias, and so on. If disputes among the underlings of a Tahitian chief erupted into violence, the chief might do little to restore order so long as the outbreak did not infringe on his interests. The state, by contrast, views the use of violence within its borders as an affront to its sovereignty. Only its own agents—its police and armed forces—are permitted to exercise violence and only toward the maintenance or restoration of peaceful internal relations.

Prehistorians have long considered that the first “pristine” or “primary” states—i.e., states that developed entirely through their own internal processes—emerged in six or seven different places: Mesopotamia, Egypt (the Nile), Mesoamerica, Peru, China, and the Indus River valley. The remainder, and by far the larger proportion, were “secondary” states, that is, states that appeared in response to or as a result of the emergence of an adjacent state. States are typically large in size. Rough estimates put the population of the Egyptian New Kingdom (1570–1069 years ago) at 3 million people, for example.⁶ With political entities of this size, stratification and political centralization undergo a further quantum leap. For one thing, the political center now controls an enormous labor pool, a state of affairs objectively manifest in the scale of monumental architecture. The enormous underground terra-cotta army constructed in the third century BCE to accompany the Chinese emperor Qin Shi Huangdi into the afterlife included more than 8,000 life-size and lifelike model soldiers and horses, a project that by some estimates took 700,000 workers 38 years to complete.⁷

The Great Pyramid at Cheops, over 482 feet (147 meters) high, built to inter the mortal remains of Pharaoh Khufu, comprised some 2.3 million limestone blocks ranging from 2.5 to 15 tons.⁸ The Greek philosopher Herodotus famously reported that the pyramid took 100,000 workers about 20 years to complete,⁹ though more recent calculations suggest a workforce on the order of 10,000 people, not counting support personnel.¹⁰

The Greek philosopher Herodotus famously reported that the pyramid took 100,000 workers about 20 years to complete, though more recent calculations suggest a workforce on the order of 10,000 people, not counting support personnel.

With the emergence of state levels of political organization, the division of labor undergoes dramatic elaboration. In egalitarian bands and great-men and big-men communities, labor

is largely unspecialized beyond the axes of age and sex. Weapons, housing, and boats tend to be manufactured by men, while karosses (animal skin garments) and baskets are manufactured by women, but otherwise families produce or provide for themselves most of what they consume. Curing and other ritual services may be specialized, and in big-man and great-man systems pottery, artwork, and long-distance trading also may be the precinct of experts, but there are no artisans who support themselves wholly or even largely by these efforts. Specialization in the latter sense only begins to emerge in complex chiefdoms like those of contact-era Tahiti. With the development of the state, however, the specialization of labor advances dramatically. The urban centers associated with the royal courts of the pharaohs and the Inca were home to thousands of artisans, artists, soldiers, and other specialists, and even the countryside saw the emergence of specialized occupations as diverse as farming, fishing, pastoralism, construction, transport, and brewing.

These trends toward political complexity underwent a further dramatic expansion with the emergence of the industrial state some 400 to 500 years ago. Facilitated by organizational and technological innovations in weaponry, transportation, written communication, and later electronic communication, the political reach of the state expanded enormously. In sixteenth-century England, the ability to manufacture and stockpile firearms in London greatly enhanced the monarch's ability to consolidate and control the realm's competing noble powers. The westward expansion of the United States would have been impossible without the railroad and telegraph. These developments, in turn, fed further expansions in the division of labor, political centralization, and stratification. As noted earlier, modern industrial states now harbor a specialization of labor so complex that occupations as esoteric as professors, personal shopping assistants, and Hatha Yoga instructors are commonplace. They are witness to staggering levels of stratification, the wealth of business magnates like Bill Gates exceeding by ten million times that of people on the poverty line. And the power centralized in the hands of government now enables genocide on a massive scale and not inconceivably could one day result in the eradication of the human race.

Ironically, as political polities have expanded across the industrial world, the most recent of political innovations, the emergence in the twentieth century of the postcolonial state, is tending toward disintegration. Rooted in the European colonization of Africa, southern Asia, and the Americas, these newly independent and often highly unstable nations represent an artificial statehood, one created by colonial fiat rather than the organic processes that propelled the emergence of "pristine" and most secondary states. As the colonizing forces of Europe swept across the globe, once autonomous band, tribal, and chiefdom communities suddenly found themselves members of a colony, expected by their colonial overlords to abandon centuries of enmity almost overnight and become a single integrated political entity. These demands could be realized only insofar as the colonized could be coerced by their colonizers into getting along with one another. With independence, however, these cobbled-together political patchworks lost the centralized colonial force that had held them together, and their indigenous leaders now

struggle with the unenviable task of trying to maintain states that were imposed from above on disparate types of political community below.

Understanding the Development of Complex Political Organizations

Set against the span of human history, the emergence and development of complex political organization seems as abrupt as it was momentous, and social scientists have struggled for years to understand the processes that compelled it. Among the earliest theories was what we might call the Intellectual Development argument, and though scholars no longer accept this thesis, it is worth a moment's consideration since it remains a common view among the contemporary lay public. In the early days of anthropology, scholars such as Sir Edward Burnett Tylor (1871) in Britain and Lewis Henry Morgan (1877) in the United States theorized that human culture had developed from an early "primitive" or "savage" phase through successive stages until it reached the modern "civilized," "scientific," or "advanced" phase.¹¹ Morgan, for instance, posited a seven-step evolutionary trajectory that began with a Lower Status of Savagery and passed through stages that included the Lower Status of Barbarism until (finally) it reached the Status of Civilization. These evolutionary schemes commonly were projected onto the world of the day. It was surmised, for example, that the Australian Aborigines were "survivals" who exemplified "savage" or "primitive man," while their social systems characterized "primitive society." The Euroamerican nations corresponded to the most recent and "civilized" forms of humanity and society. These evolutionary differences were related to the "mind," "mental condition," "intellectual state," and so on of the people in question, the lurking and unfortunate—not to mention, untenable—implication being that groups like the Australian Aborigines lacked the intellectual development of citizens in the "civilized" nations of the world. Today, this perspective still circulates in lay opinion as an assumption that political centralization and the "advance of civilization" is a kind of "invention," a product of human intelligence, and that variations in these levels of development are the result of some peoples being "backward," while others are "progressive" or "modern."

Nowadays, scholars recognize the Intellectual Development argument as at best an ethnocentric theory and at worst a racist one. Moreover, it simply does not stand up to the test. Consider, for instance, the Pacific-island societies of contact-era Polynesia. When European explorers first voyaged into the Pacific Ocean, they found almost half of this vast emptiness, from Hawai'i in the north to Easter Island in the east and to New Zealand in the southwest, to be populated by a people speaking a set of very similar languages. Nowadays we know these people as the Polynesians, and we recognize their colonizing feat as one of the most extraordinary acts of human discovery. Starting out from southeastern Asia or Melanesia some 5,000 years ago, a comparatively small population sailing sophisticated oceangoing canoes managed to spread eastward across the Pacific, discovering and populating almost

all of its inhabitable islands. Since the Polynesians all stemmed from the same ancestral population, it would follow that if cultural and political evolution were determined by intellectual development, then their contact-era levels of political complexity should everywhere have been about the same. In fact, the opposite was the case. Polynesian political organization spanned almost the entire gamut of political forms, from quasi-egalitarian systems on Niué, through petty chiefdoms on large atolls like Tongareva and complex chiefdoms on Tahiti, to a quasi state on Oahu in the Hawaiian archipelago. Clearly something affects a society's level of political complexity—and, to judge from the Polynesian evidence, it can achieve marked effects within just a millennium or so—but variations in “mental conditions” or “intellectual states” are not the issue.

As the inadequacies of Tylor and Morgan's unilineal evolution theories became apparent, anthropologists began to advance a plethora of new conjectures. These are too numerous to survey in detail, but they can be roughly categorized into three essential types: voluntaristic theories (also known as governance-by-benefit, integrative, functional, or—most recently—managerial theories), coercive (or conflict) theories, and systems (or multivariant) theories. Voluntaristic theories enshrine an essential optimism about the nature of humans and their political society. In this view, political evolution occurs when humans recognize some desirable economic, social, or military goal that can be achieved by cooperating under a centralized governance. Accordingly, they institute and voluntarily surrender their sovereignty to this authority in order to advance their well-being. Karl Wittfogel's “hydraulic” theory of state emergence is sometimes identified as an example of this enlightened self-interest argument. Observing that the development of early states seemed to coincide with the emergence of irrigation (i.e., hydraulic) systems, Wittfogel proposed that the latter was responsible for the former. Incapable of building and maintaining advanced hydraulic systems without centralized planning and direction, these societies had instituted leaders and bureaucracies to organize them, to the benefit of all. In a variation on this theme, Marshall Sahlins proposed that chiefs in Polynesia and elsewhere functioned to redistribute vital resources such as food to even out natural fluctuations caused by seasonal change, climatic variations (e.g., droughts), or occasional catastrophes (such as a cyclone or El Niño).¹² In other arguments, central authorities were instituted as a means to manage trade and markets, organize early warning systems and raise fortifications against attack, or to construct temples or other public works. In one of the most sophisticated of these voluntaristic arguments, Elman Service proposed that political evolution might occur under any and all of these circumstances.¹³

Coercive or conflict theories take a diametrically opposed view to voluntaristic theory. Whereas voluntaristic theories see political evolution

Polynesian political organization spanned almost the entire gamut of political forms, from quasi-egalitarian systems on Niué, through petty chiefdoms on large atolls like Tongareva and complex chiefdoms on Tahiti, to a quasi state on Oahu in the Hawaiian archipelago.

as motivated by enlightened self-interest, coercive theories see it as the product of coercion or violence. Whereas voluntaristic theories see leaders—big men, chiefs, kings, and emperors—as, in essence, public servants acting to advance the interests of the people, coercive theories present them as more like members of a legalized crime syndicate, exploitative agents who act to advance their own interests at the expense of the people. Karl Marx was one of the first to advance a conflict argument, and variations on this viewpoint frequently have been advanced by Marxist-inclined anthropologists such as Morton Fried and Jonathon Friedman.¹⁴ It was a non-Marxist, however, who developed the most influential coercive theory. In his circumscription theory of political evolution, Robert Carneiro observed that “pristine” states all seemed to have emerged in areas where large populations living on rich resources were hemmed in—circumscribed—by some kind of obstacle.¹⁵ The Akkadian and Egyptian empires, for example, evolved on great river systems that provided rich alluvial floodplains for farming but were hemmed in by deserts hundreds of miles wide. The kingdom of Hawai‘i appeared in an archipelago that was surrounded by more than 1,000 miles of water in every direction. Carneiro theorized that these circumscribed conditions were crucial in generating political evolution because of what happens when populations living in these areas start to increase. To begin with, the growing population begins to press on available material resources, increasing the intensity of competition. Now, in uncircumscribed environments such as the Amazon basin, this competition is relatively easily resolved: after some skirmishing perhaps, losers simply move away and take up new resources in some other unused area. Under circumscribed conditions, however, things are not so straightforward: losers are unable to easily move away because there is nowhere to move away to. What happens instead, Carneiro argued, is that losers are conquered and subjugated by winners, who then demand tribute (food and other material goods), exploiting the labor of the vanquished by forcing them to work longer hours in the fields. With this argument, Carneiro was able to sketch out an entire trajectory by which as a population increases in a circumscribed environment, one egalitarian village first conquers and subjugates another to create a petty chiefdom, one petty chiefdom then conquers another such chiefdom to produce a complex chiefdom, and so on until the entire population has been militarily unified under the coercive rule of a single powerful chief, king, or emperor.

Beginning in the 1970s, systems (or multivariant) theory attempted to unify voluntaristic and coercive theories by arguing that the evolution of political society was the product of both types of process.¹⁶ Since voluntaristic and coercive theories are polar opposites of one another, it is difficult to envisage, at first blush, how political evolution could be the product of both. How, for example, might leaders function both as dutiful public servants and as exploitative racketeers? Systems theorists pointed out, however, that there were three potential points of reconciliation. It might be, as Ronald Cohen observed, that in some places political evolution had occurred through voluntaristic processes, while in other places it had developed through coercive means.¹⁷ Alter-

natively, a society's political development might be voluntaristic in its early phases but switch over in later stages to coercive processes. Wittfogel's argument presumed, in fact, that this was the case with hydraulic societies: once a centralized authority had gained control of an irrigation system through voluntaristic processes, it then become despotic by virtue of its monopoly over a precious resource: water. Rathje and McGuire identified a third possibility: voluntaristic and coercive processes could perhaps operate simultaneously.¹⁸ In this scenario leaders are despotic and exploitative, but if they are wise they will consolidate their rule by providing benefits to those they exploit. Thus, conquest warfare on circumscribed land might result in coercive political evolution, much as Carneiro envisaged, but once in place a coercive leader might organize the construction and maintenance of irrigation systems, raising the productivity of the land to the benefit of everyone, much as voluntaristic theorists argued.

It should not be assumed that voluntaristic, coercive, and systems theories are as simplistic as they might seem when boiled down to their essentials. Nonetheless, as ethnographic, historical, and archaeological knowledge of the development of political society has expanded over the last two decades, there has been a growing consensus that the processes involved are considerably more complex than these theories imply. Scholars have become less certain about the underlying processes that propel political development, and it has become apparent that these sorts of broad-brush arguments are sometimes false in their specifics, overly simplified, or too vaguely expressed to be easily applied to specific cases. Even the basic categories on which these approaches are based—concepts such as egalitarian and big-man societies, chiefdoms, and states—are increasingly falling into question.¹⁹ Voluntaristic, coercive, and multivariant approaches remain useful as means of trying to conceptualize some of the core processes that might propel political evolution, but there has been a shift toward specific analyses of what went on over time in particular regions or societies. A lot of attention is now devoted to trying to understand the microdynamics behind, say, the emergence of great men and big men in New Guinea or the appearance of early states and later the Inca empire in Peru. The hope is that one day we shall be able to assemble from these particularistic studies a more robust and convincing overall picture of the processes of and conditions limiting or enabling political evolution.

The Future of Political Organization: Global Unification?

Given our fragile understanding of how political evolution occurred in the past, it might seem tendentious to consider what these arguments indicate about the future of complex political organization. Recognizing as incontrovertible that the Holocene has seen an inexorable consolidation of political organizations, an increase in the levels of political centralization and stratification, and an elaboration in the division of labor, however, a number of theorists have considered where these trends

Is political unification of the globe a foregone conclusion, and if so when can it be expected? If unification is not inevitable, what is it that stands to obstruct the centralizing trends of the last 10,000 years?

may be headed. Is political unification of the globe a foregone conclusion, and if so when can it be expected? If unification is not inevitable, what is it that stands to obstruct the centralizing trends of the last 10,000 years?

The principal argument against the likelihood of global unification stems from what is sometimes called the balance-of-power theory. As the biologist Richard Alexander has pointed out, one of the most important reasons why organisms form social groups is to defend themselves against predators.²⁰ By living in a group, organisms can capitalize on having many pairs of eyes and ears to detect predators, and they also may be able to repel attacks by mobbing or other collective action. Defensive grouping is especially important among humans, a species unusual for being its own most dangerous and ubiquitous macropredator. Humans are a warring species, and in Alexander's view, this characteristic locks them into a "balance-of-power race" with their neighbors. In this view, bands, villages, chiefdoms, and states are defensive organizations, and they evolve from one stage to the next as each group struggles to gain a military edge over its neighbors by expanding and developing its organizational and technological capacity. Amber Johnson has pointed to the logical consequence of such a struggle.²¹ If states evolve in opposition to one another, then we can expect political unification to continue until the globe has fallen under the control of just two superstates. At this point, however, the process of unification will cease because neither state can exist without the other. One superstate might succeed in conquering the other, but the external opposition that hitherto had unified it would then disappear, leading to its disintegration and the emergence, once again, of two or more units.

In contrast to the balance-of-power position, other theorists have argued that global unification is inevitable, and several have attempted to project its occurrence. Writing during the dark days of World War II, Hornell Hart examined data on the growth rates of past empires and of accelerative trends in the technologies of transportation and military armaments.²² His calculations indicated that by 1950, the world would either be unified under a world government or divided between two or more nearly equal rival groups, in which case a third world war would ensue. If one were to accept that the United Nations (UN) is a kind of global government, then Hart's prediction was not so far off. The frail global institution that is the modern UN was not what he had in mind, however, and the accuracy of his forecast therefore highlights rather dramatically the hazards of prediction in this field.

The difficulties are underscored by the range of unification dates calculated by later authorities. Based on the rate at which the number of world polities has declined through history, Carneiro calculated that global unification would occur in 200 to 300 years.²³ Applying sophisticated mathematical techniques to data on the expansion and contraction of 28 Eurasian empires, Raoul Naroll computed that unification was more rather than less probable within the next 200 years and close to a

statistical certainty within 1,000 years.²⁴ Finally, applying a different mathematical approach to Naroll's data, Marano (1973) projected unification between 1,500 years and 2,850 years.²⁵

Changes in methods of production have an impact on the entire structure of societies, causing numerous changes in people's lives. Industrialization was one of the most profound economic transitions of history, requiring adjustments in social organization at all levels. It increased the pace of urbanization as it became more effective to gather people into centers near factories or near investment centers and banks. Time became important, as the pace of life became determined more by the factory whistle or the railroad schedule. Fewer families functioned as economic units as family farms became less common, while having a wife at home devoted to domestic duties became a symbol of success among middle classes. We have not yet determined the full extent of the political impact of industrialization, but it is certain that nationalism, internationalism, and the current globalization all are direct results.

—Carolyn Neel

Industrialization in World History

Carolyn Neel

When we speak of the Industrial Revolution, we are talking about the dramatic changes in production that transformed societies across the world and forever altered the relationship between states. Scholars and pundits of the past have occasionally searched for the factors that prevented some areas, such as China and India, from early entry into the Industrial Age. A better question is: why should any society turn to mechanized production? Industrialization was a by-product of conditions reaching back into Europe's medieval economic ages. Today's highly mechanized production was the result of a series of circumstances setting the stage for the determined pursuit of industrialization that came to fruition in the nineteenth century. Whether this turn of events was fortuitous or not has yet to be fully determined. For most of humanity's existence, people or domesticated animals provided most of the power necessary to produce the material means of survival. True, ingenious tinkerers had long harnessed water and wind for some purposes, but if water turned the millstones and wind filled the sails to send people across the seas, humans or draft animals pulled the plows, dragged the boulders, or charged into battle. Industrialization was not an end in itself; it was the means to achieve other goals, such as faster or less expensive production in order to maximize profits.

Although the international balance of power may not have been foremost in the minds of the early tinkerers who developed the steam engine or the spinning jenny, it was a foreseeable result. Eastern Asia was definitely a center of political and economic power during the mid-eighteenth century before European industrialization. China was clearly the regional hegemon, the dominant state, exerting a powerful influence far beyond its borders. The dynamic Qianlong emperor (1711–1799) doubled the size of China and maintained a clientage relationship with China's border states. The Chinese were aware of the “western barbarians” but did not bother to differentiate between the various European states until the late eighteenth century. The British, a people on a small,

gloomy island on the western edge of the Eurasian continent, began developing machines to drain coal mines and power the looms that produce textiles and in so doing altered the international balance of power. This first round of industrialization began as a British effort to secure and hold a place in the world textile markets as well as a response to the intensely competitive European political and economic world.

The efficiencies of industrialization appealed to Britain's powerful European competitors as well, and the urge to industrialize rippled around the world. Industrial espionage increased; aggressive governments hired, cajoled, and even occasionally kidnapped British workmen.

As we consider industrialization, we are focusing on Great Britain, but it was never alone in its efforts to improve productivity. All participants in markets work to minimize costs by managing production costs. The efficiencies of industrialization appealed to Britain's powerful European competitors as well, and the urge to industrialize rippled around the world. Industrial espionage increased; aggressive governments hired, cajoled, and even occasionally kidnapped British workmen.

Ultimately, the competition that gave rise to industrialization intensified nationalism and propelled imperialism. Industrialization may not have caused the global warfare of the twentieth century, but it did make wars more deadly. However, first things first: what was it, why did it happen, and what did it cause?

Some scholars contest the term "Industrial Revolution," believing that the changes in manufacturing, transportation, and communication represent an evolution rather than a revolution. The idea that production would evolve as people discovered and adopted efficiencies does make sense, yet the dramatic changes in culture and social organization that accompanied national industrialization supports the notion of revolution. Nevertheless, regardless of individual perspectives on that matter, we all agree that *something* world-altering happened. As the British fought for a secure footing in international markets, tinkerers worked with producers and investors to increase output and decrease costs. As mechanization accelerated, productive leaps followed, accompanied by social accommodations. The efficiencies of factories and mass production drew people away from bucolic settings and the traditional support systems of the village into urban factory towns.

It is almost impossible to avoid reaching far into the past when we look for the roots of any economic transition. Economic shifts require that people are motivated to change and have access to the material resources to do so. The steps toward industrialization began in the Middle Ages; things could have gone differently at almost any stage. As market-based economies developed, people sensibly tried to hold down the costs of manufacturing and transportation in order to realize the greatest profits possible. As early as 1400, west European states were moving slowly into economies based on the exchange of money rather than barter or service, although the Hundred Years' War (actually a series of wars and guerrilla raids between 1337 and 1453) brought about economic crises in both Britain and France. During the reign of Elizabeth I (r. 1558–1603), many British merchants believed that the best hope for

sustained prosperity lay in following the Portuguese and Spanish examples, turning to the seas in pursuit of their economic interests, although admittedly Elizabethan seafaring merchants derived wealth more often through privateering (state-sponsored piracy) than by trade. In fact, it has been argued that modern-day capitalism grew from these bold pirates. Indeed, one could make a strong argument that industrialization was simply an economic tool to assist in the European drive to secure and hold a position in the international markets.

The European motivation to develop new economic systems was born after a series of catastrophes forced many European states to begin serious social and economic experimentation. The pandemics that swept across Eurasia in the fourteenth century, reappearing in Europe periodically from the Black Death of the mid-fourteenth century until the seventeenth-century Great Plague, certainly disrupted the economic organization of many European and Asian states. In an unfortunate twist of fate, the pandemic coincided with the beginning of a long period of cooler temperatures that shortened growing seasons and jeopardized food production throughout the Northern Hemisphere. The so-called Little Ice Age began in the fourteenth century and peaked in the seventeenth century. The winters in the 1590s, the 1620s through the 1650s, and the 1690s were particularly harsh. Across the Northern Hemisphere, societies faced adversity through social, political, and economic innovation, albeit with varying degrees of success. In China, the famines of the period were indications that the Ming dynasty had lost the approval of heaven, and rebellions began popping out across the land. A series of civil wars and rebellions brought the Tokugawa to power in Japan. It was the “Time of Troubles” in Russia, a period of rebellions, civil wars, and coups. In North America, five tribes formed the Iroquois Nation and began expanding their empire.

European conflicts, such as the religious wars, the Thirty Years’ War, and the English Civil War added to the misery. Adversity led to innovation. An increased food supply and an available workforce grew from these harsh conditions. With agricultural production falling, tenant farmers found themselves in severely reduced circumstances; the owners of the large manorial estates were not able to collect the usual rents. Both parties began innovating. Some landholders turned to sheep farming; woolens had been a chief British export for years and had soared in the century following the plague. This land use was very attractive; one or two shepherds were less expensive and far less trouble than a village of peasant farmers. Other landowners stayed with food production and began trying new farming methods, introducing improved methods as well as enhanced strains of plants and animals. By the late sixteenth century, agricultural yield per acre had soared. The inspiration to innovate was in place and so was the available workforce.

By 1500, feudal serfdom was almost extinct in England; wage-earning rural workers, some of whom prospered and became landowners themselves, replaced serfs. Others wound up as tenant farmers or wanderers looking for day work. With the collapse of the feudal hierarchy, a few intelligent, aggressive former peasants became yeoman farmers—commoners without aristocratic titles who held and farmed small estates—some

eventually amassing significant holdings to become members of the gentry, powerful nonaristocratic landowners who collectively owned over 50 percent of the available estates. The gentry became progressively more powerful, particularly after the civil war and revolution of the seventeenth century. A few accrued fortunes, some by rather unsavory activities such as slave trading. Financial institutions grew and prospered. Class divisions began blurring at the highest levels and intensifying in the lower ranks. Aristocratic and wealthy gentry families entered into relationships through shared business interests or marriage;

yet at the same time, resentment intensified against the burdens of the Poor Laws (which mandated a level of care for Parish paupers). Food riots and dangerous roving bands of “masterless men” aroused more antipathy for the lower economic echelon than sympathy. Nonetheless, despite intensified class resentments, an important precondition for industrialization existed: capital was available for investment in manufacturing, investors with considerable political power held it, and there was enough competition for lower-level work to keep labor expenses low.

Nonetheless, despite intensified class resentments, an important precondition for industrialization existed: capital was available for investment in manufacturing, investors with considerable political power held it, and there was enough competition for lower-level work to keep labor expenses low.

Circumstances were somewhat different in France, but the French continued to pursue industrialization. They did not develop an equivalent independent nonaristocratic elite before the French Revolution, but the bourgeoisie had been growing steadily, while taxation and special fees burdened peasant farmers. France was rich and highly populated but lacking in resources such as coal. A Frenchman designed the first steam engine in the late seventeenth century, but the need to import coal drove up costs, particularly the costs associated with metallurgy. Revolution and subsequent wars interfered with the French movement toward industrialization until Napoleon Bonaparte’s defeat in 1812. Other west European states, such as Prussia, Belgium, and the Netherlands, were moving toward economies based on more efficient production techniques. Tsarist Russia began importing British technology early on and carefully cultivated working relationships with British advisers. By 1815 Russia had its first steamship and also imported machinery until the country could start its own machine-building factories. Yet because of the internal problems in Russia, the country did not develop into a true industrial power until the twentieth century. In the United States, by the mid-nineteenth century there was a strong political focus on banking, maintaining a stable currency, and developing internal improvements in infrastructure, all of which encouraged high productivity and modern industrial capacity.

German industrialization, which is often considered part of a second wave, was generally driven by government action. Guilds and serfdom were abolished by the 1840s, but Germany remained largely dependent on foreign techniques, often gained through hiring British workingmen. State backing of heavy industry and creative business structuring

gave Germany a jump-start, and industrialization proceeded at an amazing pace. Creative banking practices aided small businesses in combined forces, often gradually forming big amalgamations. The unification of the German states in 1871 did accelerate and enhance German efforts; they were determined to meet the French and British as equals in every way, including gaining access to raw materials through imperial expansion.

Some scholars argue that the first efforts at industrialization were inspired by the organization and division of labor found on the slave plantations of the early modern era. It is certain that industrialization was in large part funded by the Atlantic slave trade. The modern bout of imperialism in Asia and Africa can be traced directly to European industrialization, as the various states attempted to find and control sources of raw materials as well as potential markets. The military advantages of industrialization were painfully obvious during the Opium Wars (1839–1842, 1856–1858), the Crimean War (1853–1856), and the United States Civil War (1861–1865). Russia, China, Japan, and the Ottomans were all inspired to industrialize as these wars and the successful imperial adventures of the industrialized West unfolded. Although they worked toward industrialization, Russia and China were only able to stabilize their efforts to any significant degree until after rebellions and civil wars toppled the Romanov (1613–1917) and Qing (1644–1911) dynasties in the twentieth century. The Ottoman empire disappeared after World War I.

Two shocks inspired the Japanese to industrialize quickly: first, the ease with which the navy of a small European island forced its will upon the powerful Chinese Qing dynasty in the first Opium war and, second, the fleet of heavily armed U.S. warships that sailed into Tokyo Bay in 1854 demanding trade and diplomatic concessions. West European powers soon joined the United States, forcing the Tokugawa shogun to make concessions similar to those made by China. Japanese opposition forces joined in overthrowing the Tokugawa, elevating the young Meiji emperor to power. Feudalism was abolished in 1868. Private investors did not act quickly enough for the enthusiastic Meiji government, so the state became dominant in the industrializing effort, funding the initial railway connection between Tokyo and Yokohama with loans from the British Oriental Bank. The railroad lines were immediately profitable, and the government worked to develop mines, using imported machinery to support large-scale production. These dedicated bureaucrats embodied a combination of Confucian ethics and Samurai drive; they were men of action determined to meet the West on its own terms. They imported about 3,000 experts from Europe—Germans, Britons, French, and even Italians—between 1875 and 1890. By 1890 Japan had become a modern industrialized state, and soon—like Britain, Germany, and France—embarked on its own imperialist ventures: fighting wars with China over Korea (1894–1895) and with Russia (1904–1905), annexing Korea in 1910, and then attempting to conquer China (1937–1945), to name a few of Japan's military adventures.

To return to our original question: Why weren't the technologically advanced states of India or China the first to industrialize? Although it is still the wrong question, it does warrant discussion. Both Chinese and

Indian artisans had developed a high level of skill in metallurgy and production of wares, from heavy equipment to luxury goods. However, neither China nor India had the sort of political stability and support necessary. The Mughal dynasty of India (1526–1858) lost its hold and began disintegrating in the early eighteenth century. The Portuguese, Dutch, British, and French had trading posts in India, and Mughal instability caused many wealthy Indian merchants and bankers to turn to the Europeans for protection. The British East India Company defeated French forces in the mid-eighteenth century and then went on to conquer Bengal in 1757. Over the next 100 years the company, a trading corporation, conquered most of what we now know as India. India was, as Peter Stearns noted, “deindustrialized” as a part of the British overall trading strategy.¹ India had not been in a position to industrialize significantly under the Mughals or their British successors.

Imperialistic foreigners and the heavy reparations imposed after the Opium Wars and the Boxer Rebellion destabilized China during a time of weak, indecisive leadership. Had the confrontations come a century earlier, China might have possessed the internal cohesion and resources to repulse foreign interference. Under the Ming dynasty (1368–1644), the large port cities of China developed robust consumer economies. There was even an existing manufacturing base, such as the huge Jingdezhen Porcelain Works, which was the largest industrial operation on the globe during the sixteenth century. It operated 1,000 kilns with 70,000 workers and used an assembly line process. There was an affluent gentry class in the sixteenth and seventeenth centuries under both the Ming and the early Qing. Roads and canals linked a very sophisticated internal market system. The reasons for China’s vulnerability to foreign economic interference have been debated for a generation or more. One of the best explanations, in this writer’s mind, comes from Mark Elvin in *The Pattern of the Chinese Past* (1973).² There had been a rapid expansion of small market towns in the sixteenth century and the total disappearance of serfdom by the eighteenth century, but this activity took place with very little technological change. Both income and profits were high; there was no motivation to change. Elvin sums it up with the phrase “quantitative growth, qualitative standstill”; China was caught in a “high level equilibrium trap.”³

There were frantic efforts to industrialize after the shocks of the Opium Wars and the loss during the Sino-Japanese War, but the Self-Strengthening Movement had little actual impact. The traditional Confucian deliberations prevented timely actions at a time when imperialistic vultures were circling. From another view, the political turmoil of the Qing dynastic decline made investors somewhat hesitant, even though there seems to have been adequate investment capital available. By the time of the Opium Wars, population had surged enough to place stresses

on agricultural capacity at a time when natural disasters and failed harvests lowered production. In 1898, for instance, levies on the Yellow River failed, flooding 2,000 villages. The Qing solution of “more effort” and opening up marginally productive areas was not sufficient. Yan Fu (1854–1921), one of the most influential scholar/activists in China, believed that China’s problems were primarily internal, with only about 30 percent attributed to foreign interference. Perhaps. However, it may have been that 30 percent that resulted in the end of dynastic China.

Industrialization’s far-reaching changes in production and access to power transformed the globe. States with the power to support industrialization thrived but took an unfortunate turn as they attempted to gain control of raw materials and potential consumers across Asia and Africa. Latin America avoided formal colonization at this time, but Latin American states were drawn into the world markets as exporters of inexpensive raw materials, importing the higher-profit finished products. Many developed a dependency on foreign banks and corporations. Although there have been some improvements in economic connections, Latin America’s uneasy relationship with the United States and various West European states has persisted. The highly industrialized consumer states were willing to support unpopular governments in order to preserve commercial relationships, which further complicated already complex internal social arrangements.

The radical social reorganization required by industrialization changed culture and social organization everywhere. International success depended on the success of domestic businesses and maintaining a healthy economy. Labor costs were the most easily controlled; women and children were the most desirable employees because they tended to be more

Labor costs were the most easily controlled; women and children were the most desirable employees because they tended to be more compliant. Wages fell, as did standards of living.

compliant. Wages fell, as did standards of living. Governments became involved in labor issues, assisting in keeping wages low. Some economists, such as David Ricardo (1772–1873), opposed higher wages or unemployment assistance, maintaining that they disrupted a divine plan: when times were good, workers would have more children, ensuring that the next generation of workers would be competing for jobs, keeping wages low. When times were bad, excess numbers would die of starvation, keeping the world in balance. Had they not already been dead, humanitarians such as David Hume and Adam Smith would have been appalled. Yet until workers began organizing for political power, their living conditions and their treatment by employers was horrifying.

In Britain particularly, most operations began as textile producers. With the new mechanized looms, working at home became impractical. It was more efficient to gather the workers in one place—the manufacturing factory—than to try to move machinery, and thus grew the factory towns. Hastily built and centering on efficiency of production rather than quality of life, these towns were crowded, dirty, and oppressive. Friedrich Engels described the appalling conditions:

In most of the working-men's quarters of Manchester, the pork-raisers rent the courts and build pig-pens in them. In almost every court one or even several such pens may be found, into which the inhabitants of the court throw all refuse and offal, whence the swine grow fat; and the atmosphere . . . on re-reading my description, I am forced to admit that instead of being exaggerated, it is far from black enough to convey a true impression of the filth, ruin, and uninhabitableness, the defiance of all considerations of cleanliness, ventilation, and health which characterise the construction of this single district, containing at least twenty to thirty thousand inhabitants. And such a district exists in the heart of the second city of England, the first manufacturing city of the world. . . . Everything which here arouses horror and indignation is of recent origin, belongs to the *industrial epoch*.⁴

Urbanization brought economic benefits but disrupted traditional loyalties, which were slowly replaced by a sense of nationalism, an ideology based on common language, culture, and history, among other things.

Industrialization, nationalism, and patriotism were interwoven. People across the world began to believe that economic development was tied to the fate of the nation. The enhanced sense of nationalism, like industrialization itself, intensified during the transition to a market economy. It is arguable that nationalism was a prerequisite to industrialization; loyalty to manor or village could not call forth the coordinated effort required in completely redesigning an economic system. Imperial expansion had an economic motive but also required a population excited by the notion of serving “Queen and Country.” Imperialists loved their empires and the machines that made them possible. Iron machines were decorated with molded ivy or flowers; cannon were given human names and celebrated by songs and poems. By the nineteenth century, success in industry and commerce became a patriotic duty, and nations willingly provided the necessary military support and protection.

Globalization—the increasingly interconnected relationships between the people of the world—is a reality in our lives. We take for granted that our material belongings may be constituted of elements from across the world (perhaps Indian cotton, wood from Brazil, diamonds from South Africa, etc.). We also understand that the financial difficulties of late 2008 destabilized markets around the world. As Dr. Gilbert writes, international processes have an increasing impact on our lives.

—Carolyn Neel

Globalization and World History

Erik Gilbert

It is often remarked that historians' interpretations of the past reflect the concerns of their time. The great historians of the nineteenth century were primarily concerned with the history of the nation-state. Economic history saw its star rise in the United States during the Great Depression, a time when the writer Thomas Wolfe (author of *Look Homeward Angel*) observed that everyone claimed to be an economist. It should not come as a surprise then that since the end of the Second World War, historians have become interested in interpretations of the past that emphasize cross-cultural exchange and encounters. The years since 1945 have been marked by the greatest expansion of planetary interconnectivity in history, so naturally we have begun to notice and emphasize those aspects of the past.

This process of ever-increasing global interconnection is usually called globalization. Unfortunately “globalization” is one of those terms that gets used in so many ways, by so many people, and in so many contexts that a concrete and universal definition of the term is nearly impossible to come by. In his book *Globalization*, Jan Aart Scholte devotes nearly all of the first 85 pages to examining the different conceptions and definitions of globalization that are currently employed in both scholarly and popular usage. He ends by concluding that none of the standard definitions is completely satisfactory and offers his own, “the spread of transplanetary—and in recent times also more particularly supraterritorial—connections between people.”¹ Scholte wisely concedes that his definition is imperfect, but we will use it, as he does, because it makes a good starting point for talking about globalization.

These “transplanetary connections” can take many forms. They can be economic in that one aspect of the new global order is the free flow of capital and goods across national borders. The years since 1945 have seen a steady erosion of barriers to trade and investment, with the result that consumers all over the planet have access to goods produced wherever labor is cheapest. A far greater percentage of what is now consumed is manufactured far from the point of consumption than was ever the case in the past. This is not exclusively a rich world phenomenon. Africans are just as likely to see Chinese-made refrigerators and cell phones and Indian-made cloth in their stores as Americans are to see Chinese-made MP3 players and computers.

Maria Guaman receives 100 dollars sent by her husband, a U.S. immigrant, at a bank in Nabon, Ecuador, March 18, 2009. The country adopted a U.S.-dollar-based system in 2000. (AP Photo/Dolores Ochoa)

Economic connections between people are not limited to manufacturing. Outsourcing of business processes, mostly but not exclusively to India, lets businesses all over the world make use of educated and skilled workers more cheaply than they can get the same workers in the United States or Europe. Writing software code, accounting, telemarketing, and data entry and processing are all easily outsourced. An interesting example of this is New York City's use of workers in the west African nation of Ghana to process parking tickets.

Likewise, capital moves almost seamlessly through the world and across borders. Cross-border investment is commonplace, and the speed at which money can flood into a place that seems to promise good returns is rivaled only by the speed with which it departs once investors lose faith in an economy. The result of this has been extraordinary economic growth in places that are in favor with investors and catastrophic financial collapses when investors decide to bail out of an economy in crisis.

Writing software code, accounting, telemarketing, and data entry and processing are all easily outsourced. An interesting example of this is New York City's use of workers in the west African nation of Ghana to process parking tickets.

People too move through the world, though with less ease than goods and capital. Even the most avid proponents of economic liberalization—that is, the removal of obstacles to the free movement of goods and capital—have been unwilling to see the movement of labor fully liberalized. The migration of people, whether for economic or other reasons, remains tightly controlled. Still, the global movement of people is at an all-time high. Workers from the poor parts of the world flood into the United States and Europe, where their labor is worth far more than it is at home. At the same time, ambitious skilled workers from Europe and North America are moving to the Persian Gulf and to eastern

Asia seeking opportunities for skilled workers with a good command of English. In addition, tourism and business travel routinely and cheaply send temporary visitors to places that would have been reachable only after an arduous and expensive journey 50 years ago.

There is a political element to globalization. Just as businesses are no longer anchored to the nation-state, the great political challenges of our time have a global component. Environmental concerns, such as climate change or the degradation of the oceans, are not issues that only affect or can be addressed by individual states. Similarly, nonstate political movements, like terrorist organizations, are global problems that transcend the confines of a particular nation-state. Even a fairly localized political organization, like Hezbollah in Lebanon, raises money from Lebanese Shiites living in places as disparate as the Ivory Coast and the frontier between Brazil and Paraguay. International organizations, most notably the United Nations (UN) but also the World Bank, the International Monetary Fund, Interpol, and the International Maritime Bureau, play an ever-growing role in trying to resolve these and other issues.

Globalization has a social and cultural side too. The presence of large groups of recent immigrants has changed the cultural landscapes of American and European cities. Foods that were once exotic and foreign have become commonplace in the West. Indian curries have supplanted fish and chips as the national food of Britain. Americans now eat more salsa than they do catsup. At the same time, Western restaurant chains and their imitators are found virtually everywhere. Nigerians eat their burgers at Mr. Biggs, Pizza Hut is ubiquitous in the Middle East, and Indians queue up for mutton burgers at various McDonalds imitators. The global reach of media means that people all over the world can watch similar television programming. Networks like CNN have a global audience, and American programming is popular in surprising places. *Baywatch* is popular in the Persian Gulf (you can enjoy it without understanding the dialogue), and sitcoms like *Friends* (with subtitles) are popular in Egypt. At the same time, local media can follow immigrants to their new homes. Mexican telenovellas are available in the United States, immigrants to the United Kingdom from southern Asia are able to follow the fortunes of their cricket teams at home, and you can catch the news from the Ukraine virtually anywhere by Internet radio. Low-cost international telephony, email, and video and cassette tapes have made it possible for migrants to stay in touch with the families and communities they have left behind. As a result, the nature of travel and long-term migration has changed. One can live in a new place, far from one's home, but still be socially connected to one's old home in ways that would have been impossible a hundred years ago.

Globalization, it seems, is the defining quality of our times. Naturally there are a number of debates about it. Probably the most charged of these is the question of who benefits and who is harmed by these new developments. From the historian's perspective, it is still too soon to be able to answer that question. Instead, this essay will focus on the origins of globalization and try to assess whether it is a fundamentally and qualitatively new phenomenon or whether it is simply an elaboration

and expansion of global interconnections that have been present for centuries.

Globalization's Past: 1500–1800

Some critics of the current thinking about globalization contend that there is little that is new about it. These critics, who are often historians, argue that there is a long history of the types of interactions that we now call globalization and that the apparent novelty of globalization

Gregory Gunn's book The First Globalization, 1500–1800, argues that many of the features of modern globalization were present in the early modern period as the European discovery of new sea routes dramatically increased global trade and cultural interaction.

is caused by the real novelty of some of the technologies that created the current intensification of global interconnection. By way of example, Gregory Gunn's book *The First Globalization, 1500–1800*, argues that many of the features of modern globalization were present in the early modern period as the European discovery of new sea routes dramatically increased global trade and cultural interaction.² Institutions like the Roman Catholic Church took on a global character in this age as

the Portuguese and Spanish empires put Catholic churchmen and missionaries into the far corners of the earth, giving the Church an early form of the global reach that organizations like the UN now wield. The Church even developed an early type of global media as it brought printing presses to its most distant outposts, often places that had never had them before. Global trade in spices, textiles, bullion, and even food (sugar) made for globally connected markets. Chinese merchants came to depend upon silver from the Americas, and the Mexican peso, the Spanish real, and the Indian rupee circulated far beyond the confines of the empires that minted them.

There were global cultural encounters as European intellectuals began to grapple with the study of the Chinese classics and with Islamic and Indian classical scholarship, a family of disciplines called Orientalism. At the same time scholars in China, Japan, and southern Asia had to come to terms with the scientific knowledge that Europeans possessed, a process that was sometimes as damaging to received wisdom there as the encounter with Asia and the Americas had been for Europeans. It was also during this era, according to Gunn, that the Portuguese language emerged as the first global lingua franca. Obviously the level of global integration increased dramatically during this period, but technology of the age saw to it that these interactions were far more limited in scope and scale than is the case now. It took years for messages to pass between Europe and Asia, global markets were mostly confined to a few commodities that could bear the cost of being aboard ship for six months or a year, and the number of people who had the opportunity and education to actually spend much time pondering the intricacies of someone else's philosophy was small indeed.

Globalization's Past: 1800–1919

After 1800 technological innovation picked up rapidly, and globalization kept pace. Primitive steam engines pumped water out of eighteenth-century mines, but in the first half of the nineteenth century steam power went through the sort of radical changes in efficiency and miniaturization that computer chips have experienced in the last 50 years. By midcentury steam engines were used in oceangoing ships for reliable passenger and mail services. By the 1870s steamships and their land-based cousins, the railways, were efficient enough that they carried much of the world's cargo. Steamships were not necessarily faster than sailing ships but were dependable. A sailing ship might make the passage in five days one time and ten days the next time. A steamship would make that same passage in seven days each time. This meant that like railways, steamships could keep to a schedule and make regular deliveries of raw materials to factories and finished goods to their markets. The result was an increasing integration of global supply chains, as Europeans manufacturers could rely on steamships to bring them regular deliveries of the materials they needed. Steamships also carried international mails in ways that were far faster and better organized (a letter was more likely to reach its intended destination) than in the past.

The advent of the telegraph meant a dramatic diminution of the time it took to communicate across long distances. By 1890 undersea cables linked the inhabited continents, and a message that might have taken many months to reach its recipient in the age of sail or some months in a steamer could pass in minutes from one side of the world to the other. To be sure, international telegrams were horribly expensive and were used mostly for essential

By 1890 undersea cables linked the inhabited continents, and a message that might have taken many months to reach its recipient in the age of sail or some months in a steamer could pass in minutes from one side of the world to the other.

business communication and by governments; there was no telegraphic equivalent of the chat room. The effect of this was to permit merchants to have more complete knowledge of global markets than ever before. For the first time in human history, market intelligence traveled substantially faster than trade goods. Before buying a cargo of cotton in Senegal, a merchant could know exactly what it would be worth that very same day in Nantes or Manchester and could make the decision of what to buy and where to send it based on that information. Prior to the telegraph, these sorts of decisions were made more or less blindly.

The expansion of European empires in the late nineteenth century coupled with Britain's ability to enforce free trade policies even in places where they were unwelcome meant that legal obstacles to trade and the movement of capital fell rapidly. European banks appeared in China, India, South America, and Africa. Telegraphs allowed these banks to process international financial transactions in hours rather than months, allowing businesses to move money globally at unprecedented rates. Global business was not the sole province of Europeans. The Indian

merchant house Cowsaji Dinshaw had offices in Bombay, Aden, Dar-es-Salaam, and Zanzibar and owned its own steamships. The Zanzibari merchant Tharia Topan had offices in Bombay and London in addition to Zanzibar. Chinese family businesses reached from southern China to branches in Southeast Asia. The Japanese soy sauce maker Kikkoman opened its first factory in the United States in 1892. All this was made possible, or at a minimum was encouraged, by the stability offered by the European empires and by a broader commitment to free trade.

This period also saw global labor migrations. Indian contract workers went to places as diverse as Trinidad, Surinam, Fiji, Kenya, and Mauritius to work on sugar plantations and build railways. Chinese laborers played a similar role in Southeast Asia, Peru, and the American West. Millions of Europeans migrated to the United States, Australia, New Zealand, and South Africa. Steamships and railways also facilitated travel for noneconomic reasons. The annual Muslim pilgrimage to Mecca, the Hajj, grew larger and more diverse during this period. The number of Indians, Africans, and Southeast Asians who could fulfill this religious obligation increased as the efficiency of steamships reduced the time and cost of long-distance travel. The late nineteenth century also saw the birth of modern tourism. Travel became part of the expected behavior of well-to-do Europeans and Americans. The postcard became popular in the mid-nineteenth century. The first round-the-world package tour was launched in 1872, and the traveler's check appeared in 1890.

Another aspect of globalization during this period was a rise in the number of international organizations. The International Red Cross and the Red Crescent were founded in 1863. The abolitionist movement and to a lesser extent the temperance movement were transatlantic efforts, though less formally organized than the Red Cross and the Red Crescent.

The Interwar Years

The decades just before the First World War were so economically integrated that some historians consider this period, rather than our own, the height of economic globalization. The war, however, brought this first great globalization to a grinding halt. Once the war started, attacks on merchant ships and the collapse of free trade agreements led to a rapid decline in global trade and migration. Even global telegraph connections broke down because they had relied on cooperation between different nations to pass messages across their territories. The British and French naturally did not allow German merchants to operate in their colonies, and once the war ended it was hard for German merchants to get back into their former businesses. The years between the world wars were also a time when protectionism was the order of the day. Nations that had once been eager free traders now worried about the economic vulnerability caused by coming to rely on resources that were not under their own control. The result was systems of tariffs meant to hinder cross-border or, in the case of the British and French,

United Nations delegates from 44 nations gather at the Mount Washington Hotel in Vermont for the Bretton Woods Conference, July 2, 1944. (Corel)

extraimperial trade. Globalization, at least with respect to trade and capital flows, diminished.

Other aspects of globalization proceeded apace. The year 1918 saw the first airmail service. The year 1919 saw the founding of Save the Children, a global humanitarian organization. Woodrow Wilson's League of Nations was the first organization that tried to embrace all of the world's nations, even if some, like the United States, shrugged off its embrace. The first transatlantic phone call, via radio link, took place in 1926.

Globalization since World War II

If the First World War set back the integration of global markets, the Second World War had the opposite effect. The pressure of war seems to act as a catalyst to human creativity. Much of the basic research for such staples of globalization as the jet engine, radar (without which air travel would be well nigh impossible), and the computer happened during the war. The precursor of the shipping container was also developed during the war, as global warfare forced the U.S. military to develop a global logistics system.

When the war ended, the leaders of the victorious nations were anxious not to repeat what they saw as the mistakes of the interwar years. One thing they especially hoped to avoid was the rise of protectionism again. Even before the war ended, the Allies had begun planning the economic recovery. They met in 1944 at Bretton Woods in New Hampshire, and the result was commitment to a steady reduction in tariffs and other obstacles to international trade. Their assumption was that nations would not go to war against their trading partners and that global prosperity might prevent another global war.

In the years immediately after the war the average tariff on international trade was 40 percent. As a result of Bretton Woods and its

successors, the General Agreement on Trade and Tariffs (GATT) and the World Trade Organization (WTO), average tariffs are now at 5 percent and still falling. Thus, most though not all of the legal obstacles to free trade have fallen. Most of the world's economic powers find free trade and globalization to be beneficial and desirable. Economically weaker nations are sometime less enthusiastic about economic globalization but find it hard to resist the pressure to participate that organizations like the World Bank and the International Monetary Fund are able to impose on them as a condition of receiving aid and loans.

The effects of these bureaucratic and legal changes have been dramatically amplified by technological innovation. The Internet, the rise of wireless phones and cheap international telecommunication, air travel, and containerized shipping have all led to what has been called

The Internet, the rise of wireless phones and cheap international telecommunication, air travel, and containerized shipping have all led to what has been called the “death of distance.”

the “death of distance.” The effects of distance have virtually ceased to exist from an economic perspective. Transportation costs represent less than 1 percent of the cost of finished goods. The price of communication has diminished to the point that mobile phone operators rarely charge extra for long-distance calls, and the price of sending an email from one side of the

earth to the other is so low that it would be hard to even calculate. Mobile phones are now more common than landlines, and their use is commonplace in parts of the world where phones of any sort are a relative novelty. For example, mobile handsets and phone cards have come to be seen as an essential feature of the bridewealth that a groom's family gives to a bride prior to a wedding in some parts of western Africa.

Containerized shipping, which uses standardized containers to hold cargo, has reduced shipping and cargo handling costs to the point that where something is made is virtually irrelevant to its price. Containers can be transferred, without being opened, to trucks or trains and taken directly from their port of arrival to the distribution center that ordered the goods. Containers are tracked and directed using the Internet, and the result of this combination of cheap communication and cheap transportation has revolutionized world trade.

From an economic perspective, death of distance is but an extreme version of the sort of global economic integration that characterized the 30 years before the First World War. On the social front the current globalization and the death of distance in personal communication do seem new and revolutionary. The Internet, air travel, and cheap international phone calls have utterly transformed what it meant to be a migrant. Immigrant communities are in regular touch with their former homes, so much so that they often seem less inclined toward assimilation than they once were. Nigerians in the United States and the United Kingdom can buy Nigerian movies with a click of the mouse. Lebanese immigrants in western Africa remain full and active members of their villages in Lebanon using not only regular phone calls but also video tapes of important events like weddings and funerals. The death of distance means that a social community can exist despite being geographically dispersed.

One effect of this has been, perversely, to strengthen rather than break down group identities. It has made west African and south Asian immigrants to Europe more rather than less conscious of their roots and community. It is easier now to avoid assimilation than ever before. Global organizations like the UN or the WTO, which strive for global integration, are rivaled and challenged by organizations like al Qaeda, which use global communications and transport for very different ends. What the future holds for globalization is difficult to judge.

The economic integration of the world in our time does not seem all that different than the economic integration of the pre-First World War era. Distance may be dead now, but its death throes began in the second half of the nineteenth century. What does seem different now is that distance is dead not just for markets but also for people. The extent to which social interactions can take place without regard to distance is revolutionary. It may be that this new development is why we are so much more conscious of globalization than people were in 1890. In 1890 Europeans rode bicycles with tires made from tropical rubber, Egyptians grew cotton to feed British textile mills, Americans drank coffee from the Middle East, and central Africans wore cloth made in Britain and New England. But they were not all watching the same movies or sending each other email. It is one thing to be in daily physical contact with objects from other places; it is another thing altogether to sit next to a person from a distant place on the bus everyday and to deal on a daily basis at work with people on the other side of the globe. It is this new social globalization, where cross-cultural interaction is a daily occurrence, that leads us to see cross-cultural interaction in the past and thus to write and read encyclopedias of world history.

Glossary

A

Absolutism A theory of government in which all sovereignty rests on a monarch or prince. In theory, the power of an absolute monarch is not limited by any legislative or judicial bodies. In Europe, this type of rule was justified by either Divine Right Theory or reason of state and was based on the assumption that the monarch knows what is best for his or her subjects.

Acheulean A type of stone tool industry characterized by the hand ax from the Pleistocene period in human evolution. Associated with *Homo erectus* and Archaic *Homo sapiens*. Named after the site Saint Acheul in France where it was first discovered.

Afrikaner South African descendant of the seventeenth-century Dutch settlers of the Cape Town Colony who speaks Afrikaans, a Germanic language derived from Dutch. The Boers (the Dutch word for “farmer”), descended from the eastern Cape frontier and were a seminomadic group of farmers who lived in the borderlands. Today the term “Afrikaner” refers to all white Afrikaans-speaking people in South Africa, which includes descendants of the Boers.

Afro-Eurasian ecumene The interacting and interrelated band of civilizations stretching from Europe and North Africa through West Asia, Iran, South Asia, Southeast Asia, China, Japan, and Korea. As such, the Afro-Eurasian ecumene (or simply the Ecumene) included most of the major civilizations of the Old World. In this usage, “Afro-Eurasian ecumene” is not just a geographical term but instead denotes a cluster of interacting civilizations.

Ahimsa Religious principle advocating avoidance of violence, associated with South Asian religious traditions—Hinduism, Buddhism, and especially Jainism. This tenet prohibits the injuring or killing of living beings.

Ahura Mazda Central Zoroastrian deity associated with goodness and truth and in opposition to the force of destruction and lies, Angra Mainyu.

Aksum/Axum Ancient African trading kingdom centered in northeastern Africa in what is now northern Ethiopia. Though a proto-Aksumite culture existed from circa 400 BCE and lasted until circa 1000 CE, the kingdom flourished from the first through the seventh centuries CE.

Al-Andalus The name given to the Iberian Peninsula while under the control of the Umayyad caliphate. Later as the area passed to other caliphates, the name became synonymous with those territories controlled by Muslims, especially as the Christians began regaining more territory on the peninsula. The name became officially nonexistent in 1492 when Granada officially became a part of the Christian Spanish kingdom.

Allah The Arabic word for God, generally used by Arabic-speaking Christians as well as Muslims, used in the monotheistic tradition of the Abrahamic religions.

Allies Countries aligned with one another during war. The best-known use of the term was during World War II, when the United States, Britain, France,

and the Soviet Union joined forces. Winston Churchill called this cooperation the “Grand Alliance,” but these countries were more commonly referred to as the Allies.

Amun An ancient Egyptian deity representing the hidden or essential aspects of the universe. When amalgamated with the solar deity Re (becoming Amun-Re), he became one of the most important deities in Egypt, with his worship centered at the temple of Karnak at Thebes. *See also* Amun-Re.

Amun-Re Ancient Egyptian deity, amalgam of two originally individual deities, Re and Amun. *See also* Amun; Re.

Anarchism A political theory that holds all forms of governmental authority to be unnecessary and undesirable. Devoid of hierarchy, an anarchist society would be based on voluntary cooperation and the free association of individuals and groups.

Ancien régime French term for “former regime” that refers to the system of government and society in France before the French Revolution of 1789. This term dates from the postrevolutionary period and was used as a way to promote the revolutionaries’ cause and criticize the past, which they viewed as a tyrannical, absolutist government.

Anthropoid Nickname for a member of the suborder anthropoidea, the so-called higher primates, that includes monkeys, apes, and humans (but not tarsiers).

Antinomianism The belief that a religious principle frees one from an obligation to follow a secular law or code. This label was often placed on groups of religious dissenters such as the Anabaptists.

Antinonianism Syncretic religion of Africa started in the Kongo at the turn of the eighteenth century that asserts that Jesus, Joseph, and Mary were all black Africans. Its main prophet Dona Beatriz was burned as a heretic in 1706.

Anti-Semitism Hostility directed at Jews on political, social, economic, and religious levels. Anti-Semitism grew in Europe during the nineteenth century, fueled by biblical interpretations assigning Jews responsibility for the crucifixion of Christ, and was central to nationalist movements in Germany and the Austrian empire. Political anti-Semitism survived into the twentieth century, most notably during the Holocaust in which Nazis attempted to exterminate all the Jews in Europe.

Apartheid South African policy of racial segregation of black citizens in townships separate from white society.

Apocrypha The original meaning of the term “apocrypha” comes from the Greek for “those having been hidden away.” This referred to certain texts that were considered too sacred or profane for any but the initiated to read. In early Christianity, the term “Apocryphal” was used to describe certain texts that were hidden because of their questionable value to the church. In the sixteenth century the word took on a negative connotation as the Protestants questioned certain books that had been included in the original Bible.

Appeasement The policy of maintaining peace through acceding to the demands of a potential enemy. The term is most often used in discussions regarding World War II and gained widespread usage as a description of British and French policies toward Nazi Germany in the late 1930s.

Aramaic Aramaic was a Semitic language closely related to Hebrew that was used extensively in the ancient Near East from 700 BCE to 200 CE.

Arianism Early interpretation of Christianity espoused by Arius and his followers in the fourth century that rejected the divinity of Christ and negated

the Trinity and was thus at odds with Trinitarianism. Arianism was popular among Roman elites, the clergy, and many of the Germanic groups.

Arminianism Named after Jacobus Arminius, a Dutch theologian, Arminianism was a Christian movement in the seventeenth century that rejected the doctrine of predestination, a tenet of Calvinism that stated that God had already chosen which people would go to heaven. Arminianism, in contrast, upheld the importance of free will and asserted that salvation was dependent on faith. Arminianism influenced the development of Methodism and Unitarianism.

Arms race Reciprocal process among nation-states of augmenting military capabilities in response to the perceived or real military buildup of antagonist powers.

Arthashastra Ancient Hindu treatise on diplomacy, economic policy, and military strategy written during the later Maurya empire, circa fourth century BCE. This treatise remained influential until the twelfth century, when it disappeared.

Aryan A group of people, now generally called Indo-Europeans by scholars, who domesticated horses and migrated from the steppe region of the Ukraine by about 4000 BCE, reaching as far west as Ireland and Scandinavia and eastward to China, South Asia, Persia, Anatolia, and the Levant. In the mid-nineteenth century, Aryans were romanticized as the ancestors of a purportedly superior race, causing many serious scholars to abandon the term. These notions and claims were thoroughly discredited by the early twentieth century.

Asantehene The title given to the ruler of the Asante empire. The first asantehene was Osei Kofi Tutu in 1701.

Asiento Beginning in the sixteenth century, the *asiento* was a contract issued by the Spanish Crown to merchants who, in return for a fee, were granted monopolies over certain trade routes and/or products.

Assimilation The process whereby individuals or groups of differing ethnic heritage are absorbed into the dominant culture of a society.

Assyria North Mesopotamian region associated with the ancient Assyrian empire (ca. 2000–745 BCE).

Aten An ancient Egyptian deity, Aten or Aton is the name for the sun god, who was thought to be manifest as the physical disk of the sun. This deity was associated with Amenhotep IV, a pharaoh who changed his name to Akhenaten and advocated a henotheistic worship of Aten, although some historians argue that this was actually the beginnings of monotheistic theology.

Atlatl A tool used to throw darts and spears with greater force and accuracy than can be done by hand. The word was coined by the Aztecs, but it is now used for all spear throwers no matter their origin, even those from archaeological sites that predate accounts of the Aztec weapons used against the Spanish.

Audiencia In Spanish America, *audiencias* were courts with criminal and civil jurisdiction over cases in Spain's viceroyalties and other colonial possessions. In addition, *audiencias* were responsible for hearing complaints against colonial officers as well as protecting the rights of the indigenous people.

Australopithecus Refers to a genus of ancient hominids; its species include *A. afarensis*, whose fossil remains date to 3.75 million to 3 million years ago. The famous 5 million-year-old skeletal remains of "Lucy," found in Kenya, are also hypothesized as being *australopithecine*. Other *Australopithecus* species include *A. africanus*, *A. anamensis*, and *A. sediba*. All of these species were

small and light of build (or gracile) compared to later australopithecenes such as *A. boisei* and *A. robustus*.

Austronesian Language group common to Southeast Asia, Melanesia (not including Papua New Guinea), Micronesia, and Polynesia. The language spread with migrations that occurred about 5,000 years ago.

Authoritarian A political system that favors a concentration of power in a leader or an elite group of people. The people governed by such a system generally lack the right to replace the leader or even to form opposition groups.

Autocracy A government in which one person or a group, like a committee or party leaders, has unlimited power. Autocratic rulers usually rely on the use of force to compel obedience in their subjects.

Auto-de-fé /auto-da-fé The practice of the auto-de-fé (from the Spanish *auto de la fe*, meaning “act of faith,” spelled auto-da-fé in Portuguese) was the sentencing phase of an Inquisition trial conducted by the Catholic Church against suspected heretics. The autos-de-fé, started in 1481 in Spain and 1540 in Portugal, were designed to instruct the populace about the dangers of straying from orthodoxy.

Avesta Holy book comprised as a collection of sacred texts of Zoroastrianism, first written in 1278 BCE in the Avestan language.

Axis The coalition of countries that united against the Allies during World War II. Though the term was first used in a 1936 agreement between Germany’s Adolf Hitler and Italy’s Benito Mussolini, the pact was solidified with a military alliance in May 1939 and incorporated such countries as Japan, Romania, Slovakia, and Bulgaria over the course of the war. The Axis alliance ended on May 8, 1945, when Germany surrendered.

Ayatollah An honorific title for a high-ranking religious leader in the Shia branch of Islam. An ayatollah (the Arabic term *ayatollah* means “sign of God”) is regarded as being an authority in religious law and interpretation.

B

Balance of power Political situation in which an equilibrium exists within a group of nations, preventing any one nation or group from forcing its economic, political, or military will on another.

Bantu A language group, characterized by the usage of “ntu,” that inhabits the eastern and southern parts of Africa and makes up two-thirds of the continent’s population. The most widely spoken Bantu-derived language is Swahili, which has over 50 million speakers. The Bantus have migrated throughout western, eastern, and southern Africa in several phases over thousands of years.

Baroque A popular style of architecture, sculpture, music, and painting in Europe from the mid-sixteenth century to the mid-eighteenth century particularly in the countries of the Catholic Reformation, including Flanders, Bohemia, and the Catholic states of Germany. Characterized by elaborate detail and dynamic movement, the baroque style is often associated with excess, exaggeration, naturalism, and sensuality. The style was also encouraged by the Catholic Church because it emphasized religious themes in an emotionally charged and easily accessible fashion.

BCE An acronym for “Before the Common Era” used to designate the years that occurred prior to year 1 CE (Common Era) of the Gregorian calendar. BCE often replaces the abbreviation BC (“Before Christ”) and is the more widely used designation among scholars.

Bedouin Originally a nomadic Arabic-speaking people who lived in the Arabian Desert, the Bedouins were divided into tribes descended from a single ancestor. They converted to Islam in the 600s and today have spread to North Africa and the deserts of the Middle East, particularly Iraq, Jordan, Saudi Arabia, and Syria. Beginning in the nineteenth century, the number of nomadic Bedouins began dwindling as economic and environmental conditions forced many to settle in the cities of the Middle East.

Berber Indigenous peoples of northern Africa who inhabit lands between the Sahara and the Mediterranean Sea and between Egypt and the Atlantic Ocean. The Berbers form a substantial portion of the populations of Libya, Tunisia, Morocco, and Algeria.

Bey Derived from the Turkish term meaning “chieftan.” The first three rulers of the Ottoman empire were known as beys before becoming known as sultans. After the establishment of the sultanate, the title of “bey” was shifted to district administrators and lower-level military governors.

Bhagavad Gita Sanskrit for “Song of God,” the Bhagavad Gita is a sacred Hindu religious text and part of the longer Sanskrit epic the Mahabharata. It is unknown when this text was written, although most historians agree that it predates the Common Era.

Bhakti Devotional path in Hindu marked by an ecstatic mysticism in which adherents attempt a permanent union with a deity such as Vishnu/Krishna, Shiva, and Durga/Kali. Poetry expressing a fervent, even romantic union with a deity, often written by women, can be found in Bhakti literature from about 500 to 1000 CE.

Bible Central book of Christian scripture that combines the Jewish Tanakh, or Old Testament (the Book of Moses, the Prophets, and Writings) with the Christian New Testament.

Bishop A bishop is a high ecclesiastical official who has the authority to ordain and confirm. The term “bishop,” which comes from the Greek *episcopus* meaning “overseer,” describes the main traditional function of a bishop, which is to govern a diocese. Bishops are the earliest attested officials of the Christian hierarchy, and their office is usually equated with that of the apostles. Only gradually did the nascent churches in the Roman empire grow enough that bishops needed help, and the offices of deacon and priest were created to provide assistants to the bishop.

Black Death European term for the pandemic that erupted in China in the 1330s and spread over trading routes throughout China to Central Asia and Europe, killing from one-third to one-half of affected populations. *See also* Bubonic Plague.

Boddhisatvas In Buddhism, boddhisatvas are enlightened beings said to remain on a lower plane of existence to offer compassion and aid to sentient beings who have not attained enlightenment.

Boer South African descendants of Dutch, Huguenot, and German settlers who were sent in the early eighteenth century to strengthen the Cape Town station in South Africa, founded in 1652 by the Dutch East India Company. The word “Boer” comes from the Dutch word for “farmer” and originally applied only to the white population living in the hinterland around Cape Town, while white men in the city were known as burghers.

Borderlands Space where two or more cultural groups from adjoining regions clash but may also meld. The distinct groups exchange goods and cultural forms and may also intermarry to form a syncretic culture that borrows from all the groups.

Bourgeoisie French word for middle class discussed in Marxist theory as the pivotal class responsible for the accelerated development of industrialization at the expense of the exploited working class.

Brahmins Hindu class of priests, part of the upper echelons of caste society.

Bubonic plague Derived from the Greek word *bubo*, meaning “swollen glands,” the bubonic plague has been responsible for several disease outbreaks around the globe. The first recorded instance of the disease occurred in the Byzantine empire during the sixth century CE. The disease was also responsible for the fourteenth-century Black Death that spread throughout Eurasia, killing one-third to one-half of the population. In the nineteenth century the plague resurfaced again in the form of a third pandemic. This latest outbreak began in central Asia and killed millions in China and India before spreading worldwide. It was not eradicated until the twentieth century. *See also* Black Death.

Buddha Indian prince Siddhartha Gautama (ca. 563–483 BCE) who renounced his wealth in pursuit of enlightenment and who espoused the principles of what would emerge as the world religion of Buddhism.

Buddhism World religion that emerged from the teachings of Siddhartha Gautama, originating in India and spreading throughout central and East Asia. Based on the Four Noble Truths, Buddhism’s followers sought to eliminate temptations and desires to attain enlightenment, or nirvana. *See also* Four Noble Truths, Noble Eightfold Path.

Bushido Japanese for “the way of the warrior,” Bushido was a strict set of rules that governed Japanese samurai behavior.

Business cycle Term economists use to describe periodic downturns in capitalist economies that can result in recessions or depressions.

C

Cahokia Site of ancient Native American civilization centered in the Mississippi River valley in what is now Illinois, characterized by a series of earthen mounds. Cahokia was initially settled in circa 600 BCE and lasted well until circa 1400 CE.

Caliph Meaning “successor” or “representative,” a caliph is the religious and temporal head of a caliphate, or Islamic state. After the death of Muhammad in 632 CE, Islam split into two factions as its adherents disagreed over who should succeed him as caliph. This disagreement led to a faction in Islam, with the Sunnis recognizing the validity of the first four caliphs but the Shia only recognizing the first two and choosing not to follow the rest. The Umayyads, the Abbasids, the Fatimids, and the Ottomans all claimed the title of caliph at one time or another.

Caliphate The caliphate was the Islamic state, ruled by a caliph, that existed from the death of the Prophet Muhammad in 632 until 1258 CE. During centuries of conquest, the caliphate spread from Arabia to southwestern Asia, northern Africa, and the Iberian Peninsula. After the last caliph of the Abbasid line was killed in a Mongol attack on Baghdad in 1258, the already-declining caliphate collapsed. A puppet caliphate in Cairo lasted until 1517, when the Ottomans invaded Egypt.

Calvinism A school of Christianity based on the teachings of John Calvin, a sixteenth-century Protestant reformer. In the seventeenth and eighteenth centuries Calvinism served as the religious basis for the French Huguenots, Scot-

tish Presbyterians, and many English Puritans, including the Pilgrims who immigrated to North America. Calvinism upheld the Bible as the rule of faith and emphasized the doctrine of predestination, the belief that God had already determined salvation or damnation.

Canaan The term used to refer to the ancient region between the Jordan River and the Mediterranean Sea prior to the emergence of ancient Israel.

Canonization Literally meaning to put a name on the list (canon) of the Roman Catholic saints, canonization is the formal process of declaring a person to have possessed heroic virtue, as proved by conclusive arguments, and to be worthy of recognition as a special servant to God.

Canton system Term for trade restrictions imposed by the Chinese Qing dynasty Kangxi Emperor, who designated specific merchant families, called the Co Hong guild, to deal with European merchants. The Qianlong Emperor, who in 1758 limited all European trade to the port of Guangzhou (called Canton by Europeans) intensified these regulations. Despite Chinese laws prohibiting the importation of opium, Canton was a major port of entry for the drug. Destruction of a shipment of Opium led to the First Opium war, 1839–1842, after which the Canton system was abandoned.

Capital If referring to a city, it is the political center of a state. If referring to finances, it is the accumulated money or other assets invested to produce profits. Can also refer to the total assets of a business.

Capitalism A highly contested term, but generally used to describe an economic system where the capital used to generate profits is controlled by private or non-government entities.

Caravansary Stations built in intervals along trade routes in Muslim-held territories that provided room and board, goods and services, and protection for merchants following central caravan routes.

Cardinal Subordinate only to the pope, a cardinal is the second highest-ranking official in the Roman curia, the papal bureaucracy.

Cartel A pact among the producers of any product that establishes cooperative agreement regarding price regulation, market share, supply, and distribution of goods. Antitrust laws make cartels illegal in the United States and many other nations because they restrict competition. The Organization of the Petroleum Exporting Countries (OPEC) is one example of a legal international cartel.

Caste A sociological term indicating a rigid hierarchy of people of the same social standing and/or economic position. One caste's members are forbidden to marry those of another. The best-known caste system is in India, with five divisions that range from the educated wealthy Brahman elite to what were formerly known as "untouchables," who perform the most menial tasks.

Catalhöyük Prominent Neolithic archaeological site located in Anatolia (modern Turkey) indicative of a flourishing settlement lasting from circa 7250 to 6150 BCE.

Catholic Reformation Also called the Counter-Reformation, the Catholic Reformation was a reform movement initiated by the Catholic Church in response to the Protestant Reformation in the sixteenth century and included theological and clerical reform and the establishment of new religious orders, most notably the Jesuits.

CE Acronym for "Common Era," used to designate the years starting with year 1 of the Gregorian calendar, while dates prior to 1 CE use the abbreviation "BCE." CE often replaces AD (anno Domini, or "in the year of the Lord").

Chavín culture A pre-Columbian culture in the north central highlands of Peru dating from around 900 to 200 BCE.

Chiefdom A society characterized by related clans or lineages that share the same culture. Lineages are ranked, and the leader of the most highly ranked lineage has the role of chief.

Chimu A pre-Incan culture along the northern coast of Peru dating from around 1100 to 1470 CE.

Christendom Geographical concept used in the Middle Ages to refer to all Christian lands as a unified entity.

Christianity A major world religion that, as presented in the New Testament of the Bible, teaches that Jesus is the son of God and that the life, crucifixion, resurrection, and ascension of Jesus redeems all humanity's sins. Christianity's principal divisions are the Catholic Church, Protestantism, and Eastern Orthodoxy.

City planning City, or urban, planning is the design of a city for the purposes of dwelling, sanitation, economy, or defense. Ancient civilizations such as Egypt, Mesopotamia, and Rome all used city planning while building their biggest cities. Medieval Europe used the planning of cities for the purpose of defense, as they were built around fortresses or castles. However, unlike for the Romans, the streets were mainly narrow and winding, with little forethought as to their placement. The Renaissance and Enlightenment brought a revival of the classical style of city building, with wide streets built on a grid system. City planning also existed in Central America, where civilizations such as the Aztecs built cities with sewer systems and running water. City planning has lasted into the modern day.

Codex An early form of the modern book. The codex, which replaced rolls of papyrus, consisted of paper or parchment bound together in the shape of a book. Its use became popular in the early days of Christianity because codex could contain large biblical texts that did not fit easily on a roll of papyrus. The term "codex" is also used to refer to a collection of laws.

Colonialism Direct or indirect political, economic, and ideological control of a region by an external power or state.

Columbian Exchange A term first used by Alfred W. Crosby to describe the meeting of cultures which followed the arrival of Christopher Columbus in the Americas, which led to the exchange of foods, plants, animals, and diseases, many of which had lasting ecological and historical consequences.

Command economy Ideological economic system promoting communalism, rejecting private ownership of the resources necessary for production. In the early decades of the nineteenth century the concept was given a revolutionary focus in the writings of Karl Marx and Fredrich Engels, which predicted the failure of capitalism and the establishment of a socialist state for the benefit of the working classes along egalitarian principles.

Communism Ideological economic system that rejects private ownership of a society's resources necessary for production, promoting communalism. In the early decades of the nineteenth century the concept was given a revolutionary focus in the writings of Karl Marx and Fredrich Engels, which predicted the failure of capitalism and the establishment of a socialist state for the benefit of the working classes along egalitarian principles.

Concert of Europe A system of diplomatic cooperation among the European monarchies—at first the Austrian empire, the United Kingdom, Russia, and Prussia—following the Napoleonic Wars. Without signing a formal agreement,

the great monarchies pledged to work together to suppress uprisings that threatened their power and territory. While the system did not succeed in crushing all rebellion, particularly the widespread revolutions of 1848, the Concert of Europe did continue as a means of international consultation throughout the nineteenth century.

Concubinage A social arrangement in which a woman, in this case a concubine, is in an ongoing matrimonial-like relationship with a man whom she cannot marry, either because he is of a higher rank or because he is already married. In places like China and the Ottoman empire, concubines had a legal status. Many families voluntarily arranged for their daughters to become concubines, as it afforded them economic and sometimes political protection. In places such as Europe, where monogamous marriage was the only status that was recognized, concubinage was afforded no legal definition and was likened to adultery.

Confucianism A belief system based on the observations of a school of thought developed by Kong Fuzi (551–479 BCE), whose name is Romanized as Confucius, and his follower, Mencius (371–289 BCE). Confucianism offers humanistic moral and ethical guidance for behavior and for proper relationships, primarily that of monarch and subject, father and son, husband and wife, elder brother and younger brother, and friend with friend. The system differs somewhat from European notions of religion, yet the system of thought developed doctrinal and ritual requirements that would place it well within the realms of both religion and philosophy. Forms or schools of Confucianism continue to play a major role in the thinking of people throughout Asia. *See also* Kong Fuzi.

Conquistadores Spanish term meaning “conquerors,” used to designate the Spanish explorers and adventurers, whether of aristocratic background or not, who conquered much of the Americas.

Conservatism A social and political philosophy that supports the maintenance of traditional institutions and resists rapid social, political, or economic change.

Constitution The collection of laws, precedents, and principles under which a government or other organization operates. The constitution may or may not be written or gathered into a single document. A constitution usually defines the nature of the government, the functions of its major branches, and its limitations and can, but does not always, include the rights of the people.

Constitutional monarchy From the seventeenth through the nineteenth centuries, numerous revolutions gradually limited the powers of traditional absolute monarchs, compelling them to share their power with legislative bodies in the creation of constitutional monarchies. Today the powers of constitutional monarchs are largely symbolic, with the real power resting in an elected legislature or parliament.

Constitutionalism Political system that is based on the idea that the government derives its power from and is limited by a basic fundamental law.

Consumer culture Describes the patterns of consumption (of commodities) within capitalist societies, particularly since the eighteenth century. After the advent of industrialization, people increasingly purchased goods produced for a mass market rather than for specific customers. As mass production satisfied more people’s basic needs more easily, consumption soon became a form of entertainment and a symbol of social class.

Consumerism Notion of consumer culture ingrained in the values of a society centered around materialism and consumption of goods and services not necessary for survival.

Corporation Business enterprise owned by stockholders who purchase shares of stock in the company but are not personally liable for the actions of said entity. Early corporations were state-licensed enterprises, often aimed at promoting trade or constructing public works projects.

Corporatism Also known as corporativism, this national economic system divides all workers and their employers into industrial and professional corporations, organizations that serve as representatives of the people in the government.

Cosmology A theory or set of theories concerning the structure and character of the universe that provides a cohesive system of meaning to a particular people or society.

Cossacks Peoples based in the southern steppe region of eastern Europe, mainly southern Russia and Ukraine, known for their horsemanship and military abilities. Cossacks were used by the tsarist state as crack troops for conquest.

Coup/coup d'état French for “stroke of state,” a coup is a sudden change in government perpetrated, often by violent means, by a small group of people. The group ousts the current leader and installs a new one, usually a member of the group.

Creditor nation A country that has a surplus in its balance of payments (its financial transactions with other nations). Basically, a creditor nation takes in more money than it pays out. A nation becomes a creditor by exporting more than it imports, earning interest on loans to other countries, enjoying investment in its economy by other nations, or a combination of those things.

Creole Creole refers to mixed ethnic, linguistic, and cultural heritage, though the particular mixture varies from place to place, often including Spanish or French heritage. In Spanish America, the term “Creole” (*criollo*) refers to white Spaniards born in the Americas. In Brazil, the term “Creole” (*crioulo*) refers to Brazilian-born Africans. In Louisiana, the term “Creole” refers to the descendants of French Acadians and free blacks.

Cro-Magnon Alternate name for *Homo sapiens sapiens*, with general reference to human fossil finds from Europe and the Near East.

Crucifixion A method of capital punishment used in many ancient societies, including those of the Persians, the Carthaginians, the Macedonians, and the Romans. The condemned person was tied or nailed to a large wooden cross and left to hang there until dead. Jesus of Nazareth is probably the most famous person to die this way.

Cuneiform Ancient writing system devised circa 3500 BCE in Mesopotamia consisting of wedge-shaped symbols, usually impressed upon clay tablets.

Cylinder seals Small stones manufactured into cylinder shapes and inscribed with images or words. When rolled on wet clay, cylinder seals would leave an impression that could identify the bearer. Cylinder seals are most associated with Mesopotamia.

D

Daimyo Powerful feudal rulers in Japanese history who held large territories of land. The Japanese word *daimyo* comes from the words *dai*, meaning “large,” and *myo*, meaning “private land.” Originally, daimyos were large landholders in a loose sense; however, by the twelfth century the term referred specifically to a military lord. Beginning in the twelfth century and continuing

for the next 700 years, daimyos provided powerful authority that translated into local coherence for Japanese society. That power rested on the daimyos' ability to control village communities by reorganizing them as well as collecting taxes for their own benefit. The daimyos sought to reduce their dependence on all governing systems that were beyond their control. Only after the daimyos were able to completely subsume autonomous villages were the Ashikaga, Kamakura, and Tokugawa shogunates possible.

Dalai Lama A religious leader to Tibetan Buddhists from the Gelug sect. *Dalai* is a Mongolian word meaning "vast sea," and the Tibetan word *lama* means "teacher." Each Dalai Lama is considered to be a reincarnation of the first Dalai Lama, Gedun Drub, who died in the late fifteenth century.

Dao The main principle of a philosophical school in China that refers to individuals finding the correct or harmonious path that will also lead to an ordered individual life and society in harmony with nature and the cosmos.

Daoism Ancient Chinese philosophy based on the teachings of Laozi emphasizing harmony with nature and quest for immortality.

Dar al-Islam Literally meaning "house of Islam," Dar al-Islam refers to those countries in which Muslims are allowed to practice their religion freely. These territories are usually ones in which Muslims represent the majority of the population.

Darwinism School of thought that follows the scientific theory of evolution proposed by Charles Darwin in his work *On the Origin of Species* (1859).

Debtor nation A debtor nation is a country that has a deficit in its balance of payments (its financial transactions with other nations); basically, it pays out more money than it takes in. A nation becomes a debtor by importing more than it exports, paying interest on loans from other countries, investing in the economies of other nations, or a combination of those things.

Decolonization The undoing of colonialism. Generally, the term decolonization refers to the post-World War II devolution of European colonial imperialism, resulting in the establishment of independent states in Asia And Africa.

Deflation A decrease in price of goods and services resulting in the increase of the value of currency.

Deforestation The process of cutting down trees in forests and jungles to provide wood products and new farmland. Deforestation is also the by-product of overpopulation. As a result of deforestation, an alarming number of species of plants and animals have become extinct or endangered.

Deindustrialization Social or economic change that occurs as a result of the removal or reduction of industrial capacity in a country or region. For example, some historians believe that the British caused the deindustrialization of India in the nineteenth century by prohibiting the sale of certain Indian products abroad.

Deism A belief system that arose in the seventeenth and eighteenth centuries and can generally be recognized as a product of the Scientific Revolution. Deism is based on the notion of a natural religion and the assumption that religious knowledge can be deduced by humans from the observation of the natural world rather than through revelation of churchly teaching. Most deists reject the notion of miracles or divine intervention, believing that God's plan is clearly illustrated through the normal workings of the universe.

Demographic revolution The increase in global population that began in Europe in the 1700s as a result of better access to food supplies and improving sanitary conditions and health that expanded globally through the nineteenth and twentieth centuries.

Desertification The steady advance of the desert resulting from deforestation and topsoil erosion. The problem of desertification has had a particularly detrimental effect on countries in Africa.

Developed nation Rich countries, located primarily in the Northern Hemisphere, that have well-organized industrial and agricultural systems. Developed nations also make use of advanced technologies and have strong educational systems.

Developing nation Countries in which large segments of the economy are relatively unsophisticated and most people are poor. There is a wide disparity between the gross national products of these countries and more industrialized nations.

Developing world Global regions currently developing industrially and lacking various economic sectors and characterized by widespread poverty.

Dhimma/dhimmi The Arabic term *abl al-Dhimma* refers to the “People of the Pact” in Muslim lands, after an edict allegedly made by the caliph Umar I. The term at first applied to Christians, Jews, Samaritans, and, rather grudgingly, Sabaeans, or star worshippers, and guaranteed tolerance of their faiths under certain conditions. Later as the Islamic empire grew, tolerance also grew to include Hindus and Buddhists.

Diaspora A diaphora occurs when a large community of people live apart from a geographic location that is considered their homeland.

Diffusionist Scholar who believes that technology, cultural change and other innovations generally originate once and spread from their place of origin as opposed to developing independently in various regions.

Diocese Administrative district established in the late Roman empire governed by a prefect. Under Catholicism, a diocese became a region under the jurisdiction of a bishop.

Direct rule A method of governing colonies or other territorial possessions whereby local rulers are stripped of their authority and replaced by representatives of the colonial power.

Divine right of kings Concept that kingship was divinely sanctioned and that monarchs were responsible only to God for their authority. This theory asserts that the king derives his power directly from God; therefore, only God can judge him. Any attempts at revolt can be seen as subverting God’s will. The concept of the divine right of kings was predominant in early modern Europe.

Domestication The act of altering wild plants or animals through deliberate breeding for human use. An essential aspect of civilization, domestication of both plants and animals began in approximately 10,000 BCE. The domestication of plants spurred on large-scale farming and thus permitted some people to give up the constant pursuit of food to specialize in other types of work. As a result, the first villages and cities formed. The domestication of animals, including cows, horses, and pigs, gave great impetus to the development of farming. Domesticated animals were also used for protection and food and as companions. Domesticated plants and animals are genetically different from their wild ancestors and are often altered in both appearance and behavior.

Dominion The term refers to legal rule or authority exerted by one entity over another. In recent years, the term “dominion” characterized the countries that made up the British Commonwealth of Nations between 1926 and 1947. These countries—Canada, Australia, New Zealand, South Africa, Northern Ireland, and Newfoundland—were autonomous within the British Empire but al-

lied under the British Crown. Because to many the term “dominion” implied subordination, it was eventually discarded and replaced in 1947 with the term “commonwealth.”

Dowry Usually land, money, or other valuable property, a dowry is a gift bestowed by the bride’s family. In some instances wives maintain control of their dowries, while in others it is given to the groom or his family. Common in preindustrial Europe, Africa, and Asia, dowries served various purposes: they sealed the friendship between the couple’s families, allowed the husband to set up his household, or even insured the wife against divorce or widowhood. Sometimes dowries also compensated the husband’s family for its payment of a bride price.

E

East India Companies Various trading companies such as those established by the English in 1600, the Dutch in 1602, and the French in 1660, for trading with India and other Asian states. The Dutch East India Company (the VOC) was the first multinational corporation as well as the first to issue stock, and in its volume of business eclipsed the British and French companies until the late eighteenth-century. The British East India Company (the EIC) was also a joint stock company, and eventually dominated the trade with China and ruled India. The French East India Company, formed late, and enjoyed some success in Asia, but not to the degree of the first two.

Ecumene From the Greek word *oikoumene* meaning “the inhabited world.” In common twentieth-century usage it has come to describe any culturally cohesive populated area, such as “the Middle Eastern ecumene” or “The Afro-Eurasian ecumene.” The term “ecumenism” is often used to convey a sense of universality and is frequently found in the context of Christianity as well as by world historians attempting to avoid ethnocentric perspectives. *See also* Eurocentric.

Elam Ancient civilization of people (Elamites) centered in central Asia in western Iran, bordering ancient Mesopotamian civilizations.

Embargo The detention of a country’s property. An embargo may be civil (the detention of national vessels in home ports to protect them from foreign depredation) or hostile (the detention of the property of a foreign state). An embargo may also prohibit exports of war materials to belligerent states or to states in rebellion in an attempt to end hostilities or in an individual state’s effort to preserve its neutrality.

Emir/amir An emir, or amir, which means “commander,” is a ruler of a specified region or territory, called an emirate. The title of emir was once reserved for military commanders of very large Islamic territories, but rulers of small territories began to use the title in the thirteenth century. The nature and extent of an emir’s rule varies. Hausaland is an example of a country divided into emirates ruled by emirs.

Empirical Notion that knowledge originates only through the senses, by observation and experimentation.

Enclosures Large medieval British estates contained villages of tenant farmers, generally near unfenced communal lands (about half of the arable land) that were used to gather firewood, nuts, berries, graze animals and supplement their gardens. In the aftermath of the Black Death, the owners of many manors realized that they could realize a greater profit raising sheep and exporting

wool than they could from the rents of tenant farmers. They began fencing these communal lands, depriving the tenants of the ability to support themselves with only their share of their crops. Although Henry VII and Elizabeth I attempted to thwart the movement, it was heavily supported by Parliament, particularly after 1700. There were three long-term results. First, the emphasis on textile production eventually led to the mechanization that fueled the Industrial Revolution. Second, it created a large body of unskilled workers trying to find employment (called the Masterless Men), keeping labor costs low for embryonic manufacturing efforts, but exacerbating class tensions. And third, some of the displaced peasants were able to accrue the skills and lands to enrich themselves and form a powerful non-aristocratic gentry class that eventually formed the backbone of the financial and manufacturing industries.

Encomienda Spanish labor system, based on feudal precedents, that allowed the recipient (*encomendero*) to extract tribute and labor from the indigenous population in exchange for the responsibility of providing them instruction in Spanish language and Christianity.

Encyclopedia A compilation of knowledge from either one field or many fields of study. The earliest known encyclopedia was titled *Naturalis Historia* and was written by the Roman Pliny the Elder during the first century CE. During the medieval period, several encyclopedias appeared in both Europe and the Middle East. The Chinese produced several encyclopedias, the largest of which was the *Yongle Encyclopedia*. Written in 1408, it was comprised of over 11,000 handwritten volumes and contained over 370 million Chinese ideograms. The modern concept of the alphabetically arranged encyclopedia that presents material in a systematic, easily accessible method first gained popularity in the seventeenth century. Many intellectuals and philosophers wanted to collect all wisdom in one place. In the Western world, the most famous of these collections was the *Encyclopédie*, which was compiled by Denis Diderot and Jean le Rond d'Alembert and contained the work of the French philosophes, with the goal of encompassing the totality of human knowledge.

Enlightened despot During the eighteenth century, enlightened despots were European kings and queens who had absolute power over their domains yet at the same time, inspired by the ideals of Enlightenment philosophy, attempted to make their governments more rational and efficient. While absolutist in nature, they no longer claimed divine right but instead said that they ruled by “reason of state,” or the idea that the monarch knew what was best for their kingdoms. Those despots were often in conflict with the clergy and the nobility, who wished to retain their traditional privileges.

Epistemology Branch of philosophy concerned with the study of the basis of knowledge, how knowledge is structured and generated.

Eschatology Philosophical or theological study and/or concern with the events related to and resulting in the end of the world.

Eugenics A pseudo-science beginning in the late nineteenth century, largely inspired by the work of Herbert Spenser, an English philosopher who believed that it was in the nature of strong states to expand and absorb weaker states, and that it was important to the evolution of humanity that they do so. Regarding individual humans, eugenicists believed that it was essential to the quality of human life that those who were genetically inferior were not allowed to reproduce. There were instances of forced sterilization in the United States as well as in Europe. The movement lost its credibility by the end of World War II because of the horrors of the Nazi extermination camps, although in disguised forms, it does continue to find its way occasionally into national discourse.

Eurocentric The practice of viewing history through a European perspective, often with an implicit presupposition of European superiority.

Evolution The theory of evolution, which maintains that all living species evolved from simple organisms in a gradual process of change over a long period of time, first received serious scientific attention after English naturalist Charles Darwin published his book *On the Origin of Species* in 1859. Darwin believed that evolution occurred as a result of the process of natural selection, whereby chance variations could lead to useful adaptations in species. Darwin's theory caused an enormous intellectual upheaval and has influenced religious, scientific, and social thought throughout the world yet has, in the best scientific tradition, withstood rigorous examination and stands as the best possible explanation.

Excommunication An extreme punishment when a member of a church or religious community commits an offense that is in severe violation of church rules. The person is then excluded from the rites, benefits, and sacraments of church membership.

Exegesis The interpretation or critical analysis of theological/religious text that discusses its significance.

Export An item that is moved out of one region or country and into another. This usually occurs as a consequence of international trade.

Extraterritoriality Guaranteed to diplomats and some international organizations, extraterritoriality describes a foreigner's immunity from prosecution over the breaking of local laws. Extraterritoriality defined the economic, social, and political relationship between native Chinese and Europeans who lived in Chinese ports in the nineteenth and early twentieth centuries. The Europeans determined that they were exempt from Chinese laws and were therefore governed by European laws exclusively.

F

Factory system The term "factory system" has two meanings, the first of which relates to trade. In the medieval period, the term "factory" referred to organizations of merchants from the same country who lived in a foreign land. These organizations were created to protect their economic interests. By the fifteenth century, the Portuguese established *feitorias*, or fortified trading posts, all along the coast of Africa. These factories spread with the Portuguese empire, and soon the English, French, and Dutch began establishing them as well. The factories served as warehouses, customhouses, and market centers. In the other usage, the term "factory system" refers to a method of production whereby workers are gathered in a centralized workplace and tasks are often broken into easy steps. The first factories, such as textile mills, depended on water power, but soon afterward steam-powered engines that depended on the burning of coal or other fuel were introduced to factories.

Fatwā A formal legal opinion given by a Muslim scholar knowledgeable about Islamic law and the Quran. Although a fatwā is not legally binding, it is authoritative and bears some religious and legal weight. During the Middle Ages, a question might arise about the legality of such actions as a farmer confiscating his son's property to prevent him from gambling or a sultan seeking to execute a Sufi. The dissenting parties would seek the sage advice of the Muslim scholar to render an appropriate ruling on their respective actions.

Fazenda Large Brazilian plantations, widespread during the colonial period. The supervision and maintenance of the fazendas was determined almost

exclusively by the *fazendeiros*, a Portuguese term meaning “plantation owners.” A *fazenda* is similar to the Spanish *hacienda*.

Femininities The ways in which different societies construct understandings and definitions of femininity that enforce the position and understanding of women in various societies.

Feminism Social and political movements advocating for the political, social, and economic equality of women.

Feudalism In Europe, Feudalism functioned as a social system, an economic system, and a political system. It is based on a diffusion of power, ruled by a king, often considered “first among equals.” Large tracts of land in the kingdom are generally held by nobles and farmed by peasants. In theory, the land comes from the king and the nobles owe him military support, and sometimes taxes. Nobles have the responsibility of protecting peasants, who repay them with agricultural production and labor services. Feudal economics are generally based on barter, cash or precious metals are rarely involved to any great extent. As a social system, it is based on well-defined roles and hereditary obligations. There is a certain amount of instability built in through tensions between powerful lords and monarchs. Although the term is sometimes used to describe non-European societies such as Japan, it should be used only as an analogy.

First World Wealthy capitalist nations, including Western Europe, North America, and some countries in Asia, such as Japan.

Five Pillars The five central tenets of Islam: profession of faith that “there is but one god, Allah, and Muhammad is his prophet”; daily prayer (five times a day); fasting from sunup to sundown throughout the month of Ramadan; charity to the poor; and pilgrimage to Mecca (the *hajj*) once in a person’s lifetime.

Fortification Set of battlements installed for defense on the battlefield or defense installations around a city or defensible position.

Four Noble Truths Foundational tenets of Buddhism: life is suffering, suffering is caused by desire, eliminating desire ends suffering, and living life based on the Noble Eightfold Path will eliminate desire. *See also* Noble Eightfold Path.

Free trade Free trade is international or domestic trade not controlled by a government or discouraged by the imposition of tariffs or taxes. Internationally, several groups of nations have formed or begun to form free trade associations that lift restrictions on the passage of goods over international boundaries.

Fundamentalism A strict interpretation of and adherence to doctrines, generally religious teachings. The term is most often applied to Jewish, Christian, and Islamic religious principles. Practitioners generally stress religious purism, strict morals and conservative social values.

G

Gender Social construct that regards sexual identity as created not by biology but rather by cultural norms.

Genocide Systematic and intentional mass murder of an entire ethnic, religious, or cultural group defined as a crime under international law.

Gentry Generally used to describe a class of prosperous families of common origin (meaning, not aristocratic). The term is used most often in relationship with Chinese or British History. In China, it describes highly educated and

prosperous families, members of which have passed the Confucian civil service examinations, thereby gaining certain legal and economic benefits for the family. In Britain, the Gentry were also commoners who earned fortunes through commerce or commercial agriculture. The aristocracy and gentry commonly intermarried.

Ghazi During the fourteenth and fifteenth centuries, the ghazis were a special cadre of Islamic soldiers who fought for the Ottoman empire against the Byzantine Christians.

Ghetto An area in a city populated by an ethnic group that is usually compelled to live there because of economic, political, social, or legal pressures.

Gilgamesh Main character in Sumerian epic poem *The Epic of Gilgamesh*, mythical ruler of the Mesopotamian city-state of Uruk.

Globalization Process of increased international political, social, economic, and cultural exchanges and networks that accelerated in the late twentieth century, diminishing the importance of the nation-state.

Gold standard The gold standard is a monetary system in which the standard unit of currency is a fixed quantity of gold or is kept at the value of a fixed quantity of gold in the country's central bank. In international trade, countries on the gold standard can maintain fixed currency exchange rates. Britain left the gold standard in 1914, briefly returned to it in 1925, and left it again in 1931. The United States went on the gold standard with the passage of the Redemption Act of 1875. By eliminating the fixed price for gold (\$35 per ounce) in 1971, President Richard Nixon formally ended the national gold standard.

Gospels A gospel is a writing that describes the birth, life, and death of Jesus of Nazareth. In the Christian Bible, the Gospels are the first four books of the New Testament (the second section). Titled Matthew, Mark, Luke, and John after the men traditionally held to be their authors, the Gospels coincide in many details but differ sharply in others. Outside the Bible there exist another 33 gospels, called Apocryphal, that are either reconstructed or preserved. In addition, there are another 23 known gospels that have been mentioned in other texts but have not yet been discovered. Despite the large number of gospels, the early Christian Church had come to a consensus on Matthew, Mark, Luke, and John, which is why most Christians consider the Gospels contained in the Bible to be authentic. Many scholars believe that the Gospel of Mark was written first, in roughly CE 70, with Matthew and Luke following soon afterward and John not written until approximately CE 100.

Grand Tour Prior to the era of mass tourism, the Grand Tour was limited to upper-class Europeans, particularly from England, who would tour France, Switzerland, Austria, Germany, the Low Countries, and Italy with a view to admiring natural wonders, learning from cultural highlights, and gleaning political insights. The Grand Tour was common in the eighteenth century. Railroad travel in the early nineteenth century opened up such travel routes to larger groups of people and blunted the cultural and political importance of the Grand Tour.

Grand vizier The chief minister of the Imperial Council within the Ottoman empire. While the grand vizier conducted council meetings, the sultan remained behind a screen. Moreover, the grand vizier was charged with the authority to speak on behalf of the sultan.

Great Chain of Being The medieval European belief—popularized by translators of Aristotle's works—in a static universe that emerged fully formed, populated with living beings created by a great designer (Plato's Demiurge or the Creator of *Genesis*). In this grand plan, all life forms were linked in an unbroken chain with the simplest forms at the bottom and the highest forms

at the top. This concept of a fixed, unchanging hierarchy was contested by the growing notions of progression and modernity during the late Renaissance and the Enlightenment.

Great Zimbabwe East African city that was the political and cultural center of a civilization we identify as Zimbabwe that spanned from 1200 to 1500, serving as a capital for trade and control of the adjoining territory.

Greater East Asia Co-Prosperity Sphere Japan announced its plan to create a “New Order” in East Asia in 1938 and in Southeast Asia in 1940 that would involve the ousting of Western colonial powers. Japan hoped to encourage its neighbors’ nationalist and anti-Western sentiments in order to gain a larger role as the region’s hegemonic power. Seizing the opportunity offered by the war in Europe, Japan planned to establish itself in Indochina (present-day Vietnam, Laos, and Cambodia), Siam (present-day Thailand), Burma (present-day Myanmar), Malaya (present-day Malaysia), and Indonesia to gain control of the region’s strategic raw materials and make Japan the region’s most influential nation.

Greater Serbian State A goal of many Serbs during the nineteenth and twentieth centuries, the Greater Serbian State was to be a nation carved out of the Balkans that would unite all Serbs. During the Yugoslavian Civil War some Serbs engaged in ethnic cleansing—the killing of innocent non-Serbian people—for the benefit of establishing a nation exclusively of Serbs.

Gregorian calendar Named for Pope Gregory XII, the Gregorian calendar replaced the Julian calendar in 1582, and is currently still in use by most of the world. The old Julian calendar has 11 months of 30 and 31 days and the month of February, which contained 28 days except for leap years, when it had 29 days. However, the calendar had too many leap years, causing it to lose days. Therefore, by 1582 the vernal equinox was occurring on March 11, which was 10 days behind. The Gregorian calendar fixed this problem by only allowing leap years in years that are divisible by 4 except centennial years, which must be divisible by 400.

Gross domestic product (GDP) An economic gauge that reflects the total value of all the goods and services produced within a nation usually over one year. The GDP includes the value of goods and services produced within a nation by foreign investors, but unlike the gross national product, the GDP does not include the value of goods and services produced outside the nation by domestic companies.

Guild The traditional form of labor organization common throughout Europe before the Industrial Revolution when all goods were produced by artisans and craftspeople. Guilds were organized by trade (goldsmiths, blacksmiths, coopers, etc.) within which a hierarchy of masters, journeymen, and apprentices saw to the training of new workers and the regulation of economic questions.

Guru In Hinduism, a guru is a personal spiritual or religious teacher. A guru invites disciples to religious practice and worship and then helps them mediate between the natural and the spiritual world. The etymology of the word “guru” is Sanskrit, and it originated in the Upanishads, the Hindu texts dating from around the tenth century to the seventh century BCE that offered interpretations of ancient scriptures. Certain Hindu sects hold that gurus are direct descendants of their deity with the power to bestow divine grace on their disciples.

H

Hacienda Large agricultural estate in Spanish Latin America. Traditionally, indigenous peasants made up the majority of the haciendas. Although they be-

gan in the colonial period, haciendas survived well into the twentieth century. Haciendas are similar to the Portuguese/Brazilian *fazenda*.

Hagiography Literally meaning “writing about saints,” as a genre such writing contained edifying and formulaic tales about the lives of Catholic saints. Hagiographic works were usually in the form of miniature treatises—in simple Latin or sometimes in the vernacular—that could be read to a congregation during a religious service.

Haiku A style of poetry that originated in Japan during the Tokugawa shogunate. A haiku is made up of 17 syllables arranged in three lines of 5, 7, and 5 syllables each. Haiku became widely popular in the seventeenth century and is still popular throughout the world.

Hajj The pilgrimage to Mecca required at least once in a lifetime for Muslims provided that they are healthy enough to complete the journey and if they or their family can afford the cost.

Harappan Ancient South Asian civilization based along the Indus River valley that flourished from the third through the first millennium BCE.

Harem The secluded part of the house or palace of a sultan, king, or male ruler. The harem was the residence of concubines, wives, other females of the household, and eunuchs. Harems were common among Indian, Middle Eastern, and West Asian royalty and still exist in some conservative Islamic societies.

Hegemony Political, economic, and/or cultural dominance of one entity by another, whether referring to internal groups or international relationships. It may involve direct action, such as colonization, but more often is the result of economic pressures.

Hellenistic Literally meaning “Greek-like,” Hellenistic refers to the time period during circa 323–30 BCE in which Greek culture, language, and attitudes became dominant in the Mediterranean and the Near East. Macedonian king Alexander the Great’s conquests caused the growth of Greek influence through the Mediterranean world as well as in Pergamum in Asia, Antioch in Syria, and Alexandria in Egypt, which all became centers of Greek culture. Hellenistic culture fused Greek and local cultures, increasing knowledge in fields such as philosophy and mathematics.

Hellenization The process of becoming “more Greek” that accompanied the expansion of the Hellenistic world. During this expansion, Greek-style cities were founded with Greek settlers, who formed the new ruling class. Although Hellenization in the West was eventually replaced by Roman influences, Greek culture remained dominant throughout the eastern Mediterranean and the Near East until the rise of Islam.

Heresy Stemming from the Latin word for a school of thought or philosophical sect, the term is used to describe any beliefs held in opposition to orthodox teachings. Generally, charges of heresy are launched against teachings in opposition to established ecclesiastical opinion or authority. The concept long pre-dated Christianity, but after the Council of Nicaea first established an official Christian orthodoxy in 325, it became an important issue in European history, playing a part in the Reformation, Inquisition, and witchcraft trials of the medieval period.

Heretic A person who embraces religious teachings that are different from and often in opposition to the teachings of the traditional orthodox teachings. The spiritual revival of the Middle Ages led to the emergence of several heretical movements.

Heterodox Doctrine at odds with existing paradigm or established theological dogma.

Hijra Flight or pilgrimage of Muhammad from Mecca to Medina in 622 CE, marking year 1 for the Islamic calendar.

Hinduism World religion centered in South Asia based on a large set of texts and social norms that influence much of modern Indian culture. Scholars argue that Hinduism, which involves a large set of many local religions, was not defined until the period of colonization when South Asians were searching for a common identity in opposition to colonial influences.

Historicism Concept that historical circumstances rather than fixed laws or the essential character of a people or region shape societies and cultures.

Historiography Literally the writing of history; however, the term “historiography” generally denotes the study of history as a discipline. Historiographic works analyze the works of different historians and schools and evaluate changing interpretations of the same events over time. Historiography looks at the purpose and audience of a historian’s work to determine biases that may have influenced that historian’s written account of historic events and issues. Historiography also analyzes the sources from which historians get their information as well as the history and theory behind historical writing.

Hittite An ancient Indo-European-speaking cultural group located in Anatolia; their capital city was Hatti.

Holocaust Term from the Greek meaning “whole burning” used to describe Germany’s systematic murder of 6 million Jews (which the Nazis termed “The Final Solution”) as well as the killing of 5 million Russians, Poles, political socialists, communists, gypsies, homosexuals, and others during World War II.

Holocene Geological era since the end of the Great Ice Age (ca. 11,000 years ago) to the present.

Homer Semimythical Greek epic poet credited with authoring *The Iliad* and *The Odyssey*.

Hominid A member of the biological family of bipedal primate mammals. Originally thought to comprise modern humans and extinct species of human-like creatures, the term “hominid” was later broadened by some scientists to include great apes (chimpanzees, bonobos, gorillas, and orangutans). The term “hominin” is widely replacing the taxonomic term “hominid” for humans and their unique fossil ancestors since the split from the chimpanzee lineage about 6 million years ago.

Hominoid Apes and humans.

Homo erectus Literally “upright man,” this ancestor of *Homo sapiens* lived from approximately 1.6 million to .5 million years ago and is a hominid associated with the Acheulian stone tool artifacts.

Homo ergaster Identified from a mandible discovered in Kenya, this contemporary of *Homo erectus* lived from approximately 1.8 million to .5 million years ago and appears closer anatomically to modern humans than *H. erectus*. Some anthropologists argue that it is simply a variety of *Homo erectus*.

Homo habilis Literally “handy man.” One of five early hominid species within the hominid genus present about 2 million years ago. *Homo habilis* had a larger brain than *H. Australopithecus* and is associated with the Oldowan tool artifacts.

Homo heidelbergensis Species name given to earliest fossil remains of hominids found in Europe. *H. antecessor* may be a variant of the same species.

Homo sapiens Modern humans, likely evolved from *Homo erectus* approximately 500,000 years ago; some anthropologists argue that Neanderthals are a branch of this species.

Homo sapiens sapiens Species directly related to modern humans that does not include any archaic subbranches.

Humanism From the Latin term *humanitas*, meaning “human virtue.” A philosophical movement that began in Italy in the fifteenth century, humanism was also called Renaissance humanism and rejected ideas of supernatural supremacy over the reasoning capacity of human beings. Humanism emphasized classical studies (called humanities), which includes rhetoric, poetry, and philosophy, and continues to influence education and philosophical thinking today.

Hundred Schools of Thought A period in Chinese history during the eastern Zhou dynasty (ca. 770–256 BCE) in which many different philosophies developed and flourished. The period was called a golden age in China and was the source of all classical Chinese philosophy. Thinkers of the period included Confucius, Mencius, Xun-zi, Lao-tzu (the founder of Taoism), and Mozu. Philosophical schools that originated during the time included Confucianism, Taoism, Legalism, and Mohism.

I

Ice Age The term “ice age” describes any of the time periods when the majority of the planet was covered with ice during the Pleistocene epoch, which lasted approximately from 1.6 million to 14,000 years ago.

Iconoclasts Those who advocate iconoclasm, which means “image breaking.” The issue of images was one of the first controversies between the Eastern and Western branches of Christianity. After Christianity found itself with two centers, one in Rome and the other in Constantinople, Byzantine Emperor Leo III (r. 717–741) became convinced that religious depictions—statuary, paintings, etc.—constituted prohibited “graven images,” and banned them. Roman church leaders, presiding over a less literate society—dissented, saying the images allowed worshipers to focus their attention and visualize the stories of the Gospels.

Imam For Shia Muslims, the term “imam” refers to the divinely inspired and anointed one who is the legitimate leader of the Islamic world. For other Muslims, the term “imam” holds a different meaning. In the Middle Ages, the term was used by Sunni Muslims to refer to the caliph or leader of the Islamic community. For Shia Muslims, the position of the imam and the caliph are mutually exclusive. The Kharijite sects, which split away from both the Shia and the Sunnis in 654, recognized only the most pious among them as imams, regardless of any other leadership qualifications.

Imperialism Extending a nation’s control and influence over the political or economic life of other nations. Imperialism can be practiced via military conquests or methods of economic domination.

Indentured labor/servitude A form of serfdom into which people entered, often unwillingly, in exchange for transport to another country or as punishment for a crime. Indentured laborers worked without wages for a period of time stipulated in an indenture, or contract, although the servants normally had their room and board provided. Many indentured servants from Great Britain and Germany arrived in the North American colonies prior to the American Revolution and the growth of slavery. After the abolition of slavery in the nineteenth century, colonial powers commonly imported indentured laborers from Asia, Africa, and the Pacific Islands to work in their colonies.

Indirect rule A colonial governing structure where an imperial power ruled through existing indigenous structures rather than by directly imposing European-style systems. It had the advantage of being familiar to colonized peoples, but there was a tendency to propagate erroneous European assumptions about local attitudes and identities.

Individualism A term coined in the nineteenth century referring to a social ideal in which the individual's freedom, rights, or independent action are paramount and more important than loyalty to one's community or company.

Indo-Europeans Also called "Aryans," Indo-Europeans from the steppe region of present-day Ukraine and southern Russia, were primarily farmers who domesticated horses as early as 4000 BCE. Over millennia they migrated across a wide swath of territory including South Asia, Iran, Persia, Ireland, and throughout western Europe, carrying their cultures and languages with them. The Indo-European-language family is one of the world's largest and includes Germanic, Hellenic, Celtic, Iranian, Anatolian, and Latin or Romance languages, along with many more.

Industrialization The transition from primarily handicraft production to mechanized production, characterized by new efficiencies like the assembly line and dependence on mechanical power (such as the steam engine) rather than on animals or humans. Industrialization appeared first in Great Britain as a reaction to market incentives, coinciding with periods when capital funds were available for investment. Industrialization is generally dependent in its nascent stage on political assistance (in order to develop canals and roadways for moving materials), an available labor force not otherwise engaged in agricultural production, and a gentry class with investment funds available.

Infanta The daughter of a Spanish or Portuguese monarch.

Inflation A rise in the price of goods and services associated with a decrease in value of currency. The reverse trend, in which prices decrease, is called deflation.

Infrastructure "Infra" comes from the Latin word for "below"; therefore, an infrastructure represents underlying structures that aid transportation, communication, and services. These can vary across historical periods but may include roads, bridges, train tracks, water and sewage, gas and electric lines, and, more recently, fiber optic and cell phone networks.

Interdict In Roman Catholic canon law, an interdict is an order—usually issued by the pope—withdrawing the support of the Roman Catholic Church from a particular individual, district, or country. When an interdict is issued, most sacraments, including communion, marriage, extreme unction, and Christian burial, are removed and prohibited. This form of ecclesiastical censure was commonly used during the Middle Ages to persuade governments to take certain actions or to instigate public rebellion to overthrow governments. In Roman law, an interdict was an order issued by a magistrate that was most commonly used in the settlements over the question of property rights.

Interventionism A foreign policy that encourages the use of force to influence the internal affairs of another nation, particularly to head off undesired changes. During the Cold War, for example, both the United States and the Soviet Union relied on interventionist policies within their spheres of influence.

Investiture A symbolic act with contractual significance performed in the Middle Ages to create or transfer property. An investiture was performed in one of two ways: the lord accepted homage from his vassal and conferred the fief (estate) while holding an object—a ring, a scepter, or a wand—to repre-

sent the act of giving (the object was retained by the lord or formally broken after the ceremony), or the lord gave the vassal the object, as its purpose was to represent that which was given. In the latter case the object might be a stalk, a piece of straw, or a banner. The symbolic object, whether kept or given, implied the lord's concession to bestow on the vassal his possession of the fief. The vassal then had the right to the enjoyment and advantages of the property (short of destroying or wasting its substance) as long as he remained his lord's man. His "holding" of the fief was thus protected against invasion.

Islam The religion practiced by Muslims, based on the teachings of the Prophet Muhammad in the seventh century. Established in the Abrahamic tradition of Judaism and Christianity, Islam is strictly monotheistic. Muslims practice the Five Pillars of Islam and accept the recitation of Muhammad, called the Quran, as their scripture. The principle division in Islam is between Sunni Islam and Shia Islam. Despite being the youngest of the major world religions, Islam currently boasts more adherents than any other religion besides Christianity.

J

Jainism Ancient religion that emerged in India in the fifth century BCE that advocates nonviolence. Vardhamana Mahavira, possibly a contemporary of the historical Buddha, is the main figure associated with the transmission of the Jainist philosophy, but Jainists believe that he was only one in a long line of teachers.

Janissaries Ottoman crack troops taken as children from Christian provinces and raised as Muslims. Janissaries were loyal to the sultan and were used throughout the span of the Ottoman empire as a major force for conquest.

Jansenism Jansenism was a movement within the Catholic Church named after the French bishop Cornelius Jansen and based on his work *Augustinus*, published in 1640. Jansen stressed the doctrine of predestination, the small number of God's "elect," and the spiritual perfection required for partaking of the sacraments.

Jihad An Islamic term that means "holy struggle." The term "jihad" refers to undergoing trials for the cause of God, striving for righteousness, and following the path ordained by God. This may be done through activities ranging from converting a nonbeliever to waging a holy war against a group or country deemed to have violated precepts of the faith or to have renounced Islamic authority.

Jizya Tax on able-bodied male non-Muslim dhimmis by Muslim theocracies. If a dhimmi converted to Islam, then he was no longer required to pay the Jizya. In some circumstances dhimmis were discouraged from conversion so the government would not lose revenue.

Joint-stock companies Investment organizations formed for the purpose of sharing the costs and risks of expensive overseas trading ventures. The costs of ships, personnel, and cargos were often beyond the reach of single investors or small partnerships. The joint stock companies formed from the seventeenth century onward allowed many investors to pool their funds. Investors were compensated after successful ventures by receiving a share of the profits proportional to their investment.

Jomon Term associated with the archaeological period preceding the development of Japanese civilization. Jomon pottery remains have been dated to 10,000 BCE and earlier.

Judaism The religion of the Jewish people, the first of the Abrahamic religions (which also include Christianity and Islam). It traces its origins to the Ancient Hebrews, a Semitic people who enter historical records during the Bronze Age in the Middle East. When the kingdom of Israel fell in the late eighth century BCE, the surviving people of the tribe of Judah remained as the eponymous founders of Judaism as a belief system.

K

Kaba A cube-shaped building in Mecca that predates Islam. The Kaba is the holiest of Muslim religious shrines, and Islamic tradition says that the building there was built by Abraham. The Kaba is where all Muslims face when praying, and the main goal of the hajj, or pilgrimage, is to visit it.

Karma A concept common to Hinduism, Jainism, and Buddhism, karma is generally seen as a moral cause and effect in which a force—good or bad—created by one’s mental and physical actions determines one’s destiny in a future life. It is believed that karma is universally applicable and can only be transcended by those who have achieved nirvana or freedom from rebirth. Although the interpretations of karma are similar on a basic level, the specifics of karma vary significantly among different sects of those Indian philosophies.

Khan Title conferred on central Asian Mongol, Tatar, or Turkic rulers. The title of khan is most famously associated with the Mongol leader Chinggis (Genghis) Khan.

Khoikhoi Southwest African ethnic group associated with the Sans, labeled “Hottentots” by Europeans in the seventeenth century, a name now considered derogatory. The Khoikhoi began losing their land and economic livelihoods when the Dutch arrived and started settling South Africa. The relationship between the Dutch and the Khoikhoi set the stage for Apartheid in South Africa.

Koine A dialect that was the common language used by speakers of the many different languages throughout the ancient Greek and Hellenistic world. Koine was based on the dialect of Attica mixed with elements of Ionic dialects, and it eventually became the language used for many literary works of the period. Koine flourished from the fourth century BCE to the fifth century CE and had widespread use in Asia, Egypt, Greece, Italy, and Sicily. The Koine dialect has been credited with aiding the spread of Christianity because the gospel could be taught and read in many different regions due to knowledge of that universal dialect. Koine forms the basis for the modern Greek language.

Kong Fuzi Romanized as “Confucius,” Kong Fuzi (551–479 BCE) and his follower Mencius (371–289 BCE) formulated the philosophical system of Confucianism, which has had a major and lasting historical impact in Asia, particularly in China, where it was the official state ideology from the Han through the Qing dynasties. Confucianism offers humanistic moral and ethical guidance for behavior, with the goal of harmonious relations between that of monarch and subject, father and son, husband and wife, elder brother and younger brother, and friend with friend. Confucianism differs somewhat from European notions of religion, yet the system of thought developed doctrinal and ritual requirements that would place it well within the realms of both religion and philosophy. Forms or schools of Confucianism continue to play a major role in the thinking of people throughout Asia. *See also* Confucianism.

Koran *See* Quran.

Kshatriyas Military and ruling elite of Hindu caste system; one of the four varnas.

Kulak Prosperous peasants in Russia who acted as moneylenders, landlords, and village administrators. After the Russian Revolution of 1917, the communist regime tolerated kulaks until the drive for the collectivization of agriculture began in the late 1920s. As the government seized the kulaks' land, the kulaks were either arrested or forcibly relocated.

Kush Egyptian term for Nubia, the region along the higher Nile River valley.

L

Labor movement Political and social movement that emerged in Europe and the United States in the nineteenth century and was geared toward attaining better living and working conditions as well as greater political representation.

Labor union Organizations developed that combined both craft and non-skilled workers together to work toward attaining concessions from corporate management through negotiation or organized strikes.

Laissez-faire A French expression generally translated as "let it be." It is an economic theory based on the operation of unrestricted market forces. The idea is often associated with Adam Smith, but was popularized in the late seventeenth century by French finance minister Jean-Baptiste Colbert. The term is still popular with those who generally advocate "free markets" without significant government regulation.

Late Antiquity Period in world history (250–700 CE) preceding and overlapping with the early Middle Ages, particularly used by studies of the end of the Roman empire, the emergence of the Byzantine empire, and relations with Germanic kingdoms and the greater Eurasian ecumene.

Latifundia Large agricultural estates owned by Roman elites and worked by slaves and tenant farmers. Similar to the Spanish haciendas or Portuguese fazendas, these quasi-feudal estates depended on the confiscation and consolidation of land and the labor of slaves or serfs to achieve their goals of mass production and turning a profit.

Legalism Chinese philosophy associated with Xunzi (298–238 BCE) and implemented by the Qin dynasty (221–206 BCE). Xunzi, looking at the combative world of the Warring States, concluded that human beings are selfish and care only for their own interests and that it takes strong discipline to bring order to a society. He advocated establishment of clear, well-publicized standards of conduct, with strong punishments for those who deviated. Although legalism was disavowed by the Han dynasty, there has been a surviving (if unacknowledged) strain throughout Chinese history.

Liberalism Historically, liberalism was a political stance opposing state regulation. British laissez-faire liberal economists, for instance, wanted to be rid of all government oversight of finances. Today in the United States, liberalism is a political ideology based on support for civil rights, tolerance for social and political change, and the advocacy of government action to improve individuals' welfare.

Lithic Stone artifact or tool. The term "lithic" can also denote what was once called the Stone Age. The term "Paleolithic," for example, simply means "Old Stone Age."

Little Ice Age An ice age that began in the fourteenth century and peaked in the seventeenth. Experts suggest that either increased volcanic activity or a

decrease in sunlight caused the onset of this long trend. Glaciers increased in size during this period, and recorded snowfall levels increased while temperatures decreased. Storm belts, which normally flowed westward, instead moved southward, which resulted in colder climate conditions in northern continental areas. It was not until 1850, the beginning of the Industrial Age, that warming trends reemerged.

Littoral Coastal regions or adjacent regions along a coastal region.

M

Madrasa/madrese A school in which any of the Islamic sciences, including Islamic law, are taught. The word itself means “place of study.” In the Middle Ages, the madrasas evolved out of independent study circles. Eventually, charitable endowments called *waqfs* provided permanent structures for these circles and even attached dormitories and sometimes stipends for teachers and students. Madrasas became centers for exchange and communication among members of the learned classes of the Islamic world and as such became crucial for the forging of communally accepted consensus on important questions of law and other matters.

Mali West African trading empire forged in the thirteenth century by Sundiata Keita “the lion prince” upon his return from exile. Peaking in the early fourteenth century under Sundiata’s great-nephew Mansa Musa, Mali became widely known for the wealth of its rulers and its control over west African trade, especially in gold.

Malthusianism Named for the eighteenth-century English economist Thomas Malthus, Malthusianism is the belief that the all animal and human populations will grow to the limits supportable by available food sources, which will mean that times of bounty will occasion population increases unsustainable when available resources return to normal, leading inevitably to periods of famine and wars.

Mandarin Derived from the Portuguese word *mandarim* meaning “to govern,” mandarin was a Western term for a member of the educated class in China, from whom the civil service bureaucrats were drawn. A competitive examination system ensured that only the most highly educated individuals became bureaucrats. The term Mandarin also refers to the dialect that became the dominant language in northern China. Members of the bureaucracy were required to speak and correspond in Mandarin, regardless of the part of China in which they served.

Mandate of Heaven The Chinese concept of political legitimacy, the belief that authority to rule was granted and maintained by Tian, or Heaven, and would be withdrawn if there were signs that rulers were shown to be unfit. Signs could be famines, wars, rebellions, or any other signs that nature was displeased. Written records of the philosophy date back to The Zhou dynasty (1045–256 BCE), but it may have existed earlier.

Manichaeism Religion founded by Mani in the third century CE that combined Zoroastrian and Christian elements.

Manifest Destiny Belief and ideology popular in the nineteenth century that the United States had a divine duty to expand westward toward the Pacific Ocean.

Manor A nobleman’s estate during the Middle Ages. Manors were the normal social and political unit during that period and were virtually self-sufficient,

with the population producing most of what it consumed. The noble who held the manor exercised jurisdiction over the local population, allowing him to dispense justice to the people. The local population consisted of both free and servile individuals. The lord had greater authority over the servile population. Free individuals usually paid monetary rent to the lord.

Mansabdari system Similar to *devsirme* in the Ottoman empire, the mansabdari system was established in the Mughal empire in the seventeenth century to create a hierarchy for the imperial military officers who received a salary. Its primary purpose was to oversee the tax system.

Manumission The legal term indicating the official release of a person from slavery.

Maoism An influential strain of communist thought that originated with Mao Zedong, a communist revolutionary in China. Maoism adapted the precepts of Marxist-Leninist philosophy to the conditions of China. Mao focused on the revolutionary potential of the peasantry (rather than industrial workers) as well as strict organizational principles, and he emphasized the importance of armed struggle.

Market economy Also known as a free market economy, it is the belief that the laws of supply and demand will function to keep economic systems from going too far in any direction, and that basic economic decisions derived from market activities will always be more effective and sophisticated than any results of government intervention.

Martyr A person who dies for her or his faith. The term is derived from the Greek word for “witness,” but it came to mean someone who attested to her or his faith when doing so meant certain death. Martyrs were venerated by early Christians, and their relics and tombs came to be considered sacred. The martyrs’ names were collected, and stories of their tortures were written down to encourage and serve as ideal conduct for other Christians.

Marxism Ideological and economic philosophies derived from the works of Karl Marx and Friedrich Engels. Marxists believe that class struggles for material resources has shaped history. They argue that in the capitalist phase, upper classes and wealthy capitalists will exploit workers, or the proletariat, and will continue to do so until workers organize to seize the means of production. Although popular as an economic theory in the nineteenth and early twentieth century, Marxism has fallen from popular favor with the dissolution of the Soviet Union and the transition of China toward free-market capitalism.

Marxism-Leninism The communist philosophy of Vladimir Lenin that reinterprets Karl Marx’s philosophy in three ways. First, revolution must be violent to succeed; second, revolution is possible because of large peasant and laboring classes; and third, revolution must be controlled by a group of dedicated revolutionaries who will not sell out the revolution before it is completed.

Marxist revisionism An adaptation of Marxist ideology originally set forth by Eduard Bernstein (1850–1932), in which the notion of an imminent collapse of capitalism was abandoned. Bernstein and others noted that in some areas (such as Germany) the working classes seemed to be accruing power rather than falling into deeper misery and that it appeared that a violent revolution was becoming less likely. The revisionists believed that industrial nations were moving toward a type of social democracy that combined private initiative and social reform.

Masculinities Social constructions of expectations, roles, and archetypes of manhood associated with cultural expectations of gender roles for men in a given society.

Mass media Combining the influence of both the broadcast media and the print media, the mass media—television, radio, newspapers, magazines, and the Internet—are together among the most powerful methods of communicating a message to a large group of people. The massing of media began in the late nineteenth century with the development of large-circulation daily newspapers.

Mass tourism With increased industrialization in the late nineteenth century, people had more money and time with which to travel. British businessman Thomas Cook organized the first group tour in 1841, a train trip to a temperance meeting. He began actively arranging trips for profit in 1845 and pioneered the mass tourism industry, taking groups to destinations all around the world. In the contemporary world, tourism is considered one of the world's largest industries.

Materia medica Latin term that refers to collected knowledge of medical and healing practices.

Material culture Archaeological term that refers to the physical remains specific to a cultural group or people. The term can be applied to contemporary culture as well as that of the ancient world.

Matrilineal The ancestral lineage derived from one's mother's family. Matrilineal societies, in which inheritance is traced through the mother's family, are common worldwide, notably in such North American Indian communities as the Iroquois and in the Nayar culture in India. The role of a mother's brother retains special prominence, as he is the male of highest authority. In addition, property is passed down through one's mother. Matrilineal cultures are not necessarily matriarchal, however, as the males still retain property and power.

May Fourth Movement Named after the student protests in Tiananmen Square in Beijing on May 4, 1919, the May Fourth Movement began in protest of the terms of the Treaty of Versailles, which punished Germany by turning over the northeastern Shantung Province to Japan instead of returning control to China. The strike galvanized anti-imperialist and nationalist sentiment in China.

Megalith An enormous stone used to construct Neolithic Age and Bronze Age monuments. Those monuments include single standing stones, lines or aisles of stones, stone circles, and tombs. They were for the most part clearly meeting places, some constructed following astronomical alignments that suggest rituals at specific times of the year. Archaeologists have also found evidence of sacrifices at some of those sites. These stones appear to reflect a particularly Neolithic religious sensibility that ranged through much of Europe, and successive cultures continued to regard the megalithic monuments as sacred. Early monasteries often integrated standing stones, circles, and tombs into their ritual life, and some monks constructed monasteries at the site of megaliths.

Meiji Restoration A period of dramatic change in Japan that began in 1868 with the overthrow of the Tokugawa shogunate in favor of the young Meiji emperor in 1868. This change was brought on by the threat of Western intervention in Japan. Meiji leaders realized that industrialization was needed in order to compete with the West. The Meiji government sought to westernize and strengthen Japan through a centralized government.

Mercantilism An economic theory that accompanied monetization of the economies in western Europe during the sixteenth and seventeenth centuries and depended on government intervention to accumulate national wealth through a balance of trade that encouraged exports and discouraged imports in order to maintain high levels of bullion. This balance was achieved by de-

veloping and regulating production, granting industry monopolies, imposing tariffs on imports, and establishing and using colonies as sources of raw material for production and as markets for their own exports.

Mercenary Paid professional soldiers hired to defend locally or to serve a foreign ally.

Meritocracy A system of government in which people are given the opportunity to achieve and advance within the governmental structure through an evaluation of personal skills and qualifications. Napoleon I attempted to establish a meritocracy in nineteenth-century France, which was the precursor to the contemporary civil service system.

Mesopotamia Meaning “between the rivers”—the Tigris and Euphrates rivers—where myriad civilizations developed during much of Antiquity.

Messiah Literally, the term “messiah” refers to the anointed during most of Jewish history. Messiah came to indicate a savior who would deliver Israel from its troubles and bring it into the promised union with Yahweh. The form and role that Israelites expected the messiah to take differed according to circumstances. Some expected him to be a king, like King David, while others expected him to fulfill a more spiritual priestly role. Most Jews, however, believed that Yahweh would send a messiah who would right all wrongs. In the New Testament, the word “messiah” is rarely used. Instead, the Greek equivalent of Christ was used. The non-Jews who received the apostles’ message eventually accepted Christ as another name for Jesus of Nazareth and not a title signifying that he was the messiah.

Mestizo Literally meaning “mixed,” “mestizo” is a Spanish term used to identify Spanish-speaking people of mixed Indian and European descent. By the nineteenth century, mestizos made up a major portion of the population in Spanish and Portuguese America.

Metaphysics The origins of the word in Greek mean “beyond physics.” Metaphysics is the branch of philosophy concerning the ultimate nature of reality and human existence.

Métis One of the aboriginal groups in Canada. The Métis people are descended from mixed European and First Nation ancestry. While historically the name was used to describe all people who fit this description, the Métis now identify themselves as a separate group and have the same status as other First Nation and Inuit people.

Metropole Dominant region in a colonial relationship with the colony or colonies subordinate to the metropole.

Middle Passage The middle part of the three-part journey taken by slave traders in the seventeenth- and eighteenth-century Atlantic slave trade. The traders first carried goods to Africa, where they traded the goods for slaves, and then started across the Atlantic Ocean to the Americas, where they exchanged the slaves for other goods and departed again for Europe. The middle part of the voyage saw the newly enslaved Africans shackled and packed tightly into tiny areas, where they were subject to disease. Slaves who would not eat or who attempted suicide were often tortured. Mortality rates were high; it is estimated that between 10 percent and 20 percent of Africans transported through the Middle Passage lost their lives.

Mihrab In Islamic mosques, the mihrab is a niche in the wall of the *qibla* (the direction which one faces in order to pray toward the holy city of Mecca). Often, the mihrab is beautifully and ornately decorated. Mihrabs first appeared during the Umayyad dynasty in the reign of al-Walid I (r. 705–715) and

may have been adapted from the prayer niches found in Christian churches. The mihrab helps to orientate the worshiper during prayer, indicating the direction of Mecca even in an unfamiliar mosque.

Militarism The view that military power and efficiency is the supreme ideal of the state. Militarism was exemplified by the leadership of Otto von Bismarck as he consolidated governmental power and strengthened the Prussian army during the late nineteenth century. Militarism, combined with the military alliances and imperialism of the late nineteenth century, was a main cause of World War I.

Millet Autonomous community within the Ottoman empire.

Minaret Minarets are slender freestanding towers that stand at the corners of a mosque. A mosque may have from one to six minarets, connected to the mosque at the base and rising in a series of stages, each marked by a balcony. Stairs either on the inside or outside lead to a dome or pavilion at the top, where a crier stands five times a day to call Muslim worshippers to prayer. Designed to be “landmarks of Islam,” visible from a distance, minarets were a prominent part of the mosques built by the Ottoman architect Sinan.

Minoan/Minoan Pre-Classical Aegean civilization that emerged in Crete from 2200 to 1500 BCE that is mostly associated with the site of Knossos.

Mir In tsarist Russia, the mir was a semiautonomous community of peasants that elected its own officials and distributed its land among peasant families. The peasants of the mir were nevertheless subject to numerous restrictions and were required to make payments to land-owning families. The mir remained as an institution after the 1861 emancipation of the serfs.

Mita The compulsory rotational labor draft (corvée) system used in the Andes by the Incas that was later adopted for use by the Spanish in the Americas.

Modernity The idea that the present time represents a break with the past first appeared as Renaissance humanists represented their time as a new age. Nevertheless, it should be understood as an attitude toward the present rather than a reference to any specific era. The period described by the term varies according to the temporal framework of the person using it, but is always used to underscore a break or discontinuity between past and present, generally depicting the present as an improvement.

Modernization Changing a society through the introduction of industrialization, technological infrastructure, and consumer cultures.

Monastery The home of any community of monks or nuns. Unlike a hermitage, where a single religious individual often lived alone, at least two persons have to reside together in a monastery. A monastery had two main sources of protection: it was normally associated with a local ruler or noble family (often, those lay protectors had the right to appoint abbots and abbesses from their own kin), and it was made sacred by the reputation of its patron saint. Many religious traditions, including Buddhism, Hinduism, Islam, Judaism, Christianity, and Taoism, have adopted monasteries as sites of religious communities.

Monotheism A religious or theological belief that only one god exists, not to be confused with henotheism, which centers on the worship of only one god while acknowledging that others may exist.

Mosque Any Muslim place of worship. The first mosques were sacred plots of ground modeled after the courtyard of the Prophet Muhammad’s house in Medina, Arabia. Besides being places of worship, mosques were often used as courts of law, libraries and schools were sometimes attached, and people gathered at them for political and social functions. Mosques differed from Christian

churches in that ceremonies surrounding marriage and births were not performed there.

Mousterian tools A style of stone tools created by Neanderthal people in Europe from circa 70,000–30,000 BCE. The name comes from a Paleolithic Age rock shelter known as Le Moustier in France, where a large number of flint hand axes, racloirs (a type of blade used for scraping), and spear points have been found. The tools were produced by flaking off chips of stone until the tool reached the shape and sharpness desired. Archaeologists have found similar tools at sites throughout Europe, the Near East, and North Africa.

Muhammad (570–632 CE) Arabian merchant, military leader, and central prophet and founder of Islam.

Mulatto People of mixed black and white ancestry. Mulattoes faced varying social restrictions in different regions of the Americas and other Western countries. Within the black community, mulattos were often privileged. They sometimes passed into the dominant white community because of their physical characteristics that allowed them to appear white.

Multinational corporation (MNC) A corporation that has branches located in more than one country. Multinational corporations became increasingly common beginning in the middle of the twentieth century. At that time, many corporations founded in developed nations began opening branches in other developed nations as well as in developing nations, where cheap labor was readily available.

Mycenae/Mycenae Late Bronze Age civilization based in southern Greece (on the Peloponnesian peninsula) that flourished from 1400 to 1200 BCE.

N

Nara period Named for the early capital of Japan during 710–784 CE, the Nara period followed the Taika reforms, which were designed to codify Chinese policies into Japanese law. During the Nara period, those policies were implemented. The subsequent rise of a Japanese bureaucratic class, innovations in medicine, and the refinement of Buddhist art, architecture, and sculpture all had direct roots in Chinese culture, although overt Chinese influence started a gradual decline during this time. The Nara period drew to a close in 784 when the Japanese emperor Kammu, fearing that the government was growing overly influenced by the strong Buddhist monasteries in Nara, briefly moved the country's capital to Nagaoka-kyo and a decade later to Heian-kyo (present-day Kyoto).

Narrative A form of history presented so as to give an account of a series of events or developments, establishing connections or noting discontinuities, as opposed to theoretical histories that use selected events, persons, or ideas to support an underlying proposition. To fill in the historical record, historians can also turn to primary source narratives, which might be oral or written autobiographical records of individual or collective experiences.

Nationalism Political and cultural ideology that emphasizes unity among people in a particular geographic area based on shared cultural and linguistic traditions and values. Some varieties of nationalism can emphasize a unity based on ethnicity or religion and at times project hostility toward foreigners or groups within the same region that do not share those characteristics.

Nationalization The process of a government taking possession of privately owned businesses and industries.

Nation-state A sovereign political system in which the people, in general, share a common history, ethnicity, culture, and language. In other words, the territory occupied by a certain group of people (or nation) is the same as the territory (or state) controlled by their government. France and England were among the first modern nation-states, while Slovenia and Croatia are two of the newest nation-states.

Natural law A concept that can be traced to ancient Greek philosophers and insists that reason discloses that certain moral rights are engrained from nature. This concept eventually melded with the notion of Natural Rights, popularized during the Enlightenment in Europe with John Locke's enunciation of the right to life, liberty, and property.

Neanderthal/Neandertal Technically, *Homo sapiens neanderthalensis* refers to an archaic form of *Homo sapiens* dating to between 100,000 and 33,000 years ago. A study of *H. neanderthalensis* DNA now suggests that some interbreeding occurred between this species and modern *Homo sapiens* outside of Africa.

Neo Europes Term coined by Alfred Crosby in reference to European settler colonies that were established along similar political, economic, and social structures as those in Europe.

Neo-Confucianism A resurgence of Confucianism that developed first in the Tang dynasty (618–907) and flowered during the Song dynasty (960–1279). It is sometimes described as an attempt to reconcile Confucian, Daoist, and Buddhist concepts and practices but developed as a distinct phase of Confucian thought, emphasizing the relationship of individuals to the whole and declaring that abstract philosophy was useless until incorporated into moral behavior. Neo-Confucianism became the basis of civil servant examinations in the Song dynasty.

Neolithic Age Refers to Prehistoric periods when settled, agricultural ways of life begin to supersede nomadic and seminomadic lifestyles; there were various Neolithic periods in antiquity, depending on when this process occurred in each region.

Neolithic Revolution Although the term “revolution” may be a misnomer, as the change occurred over many centuries, the Neolithic Revolution refers to the transformation of human societies from hunters and gatherers to farmers and herders (food producers) and is usually used in reference to the Near East and Europe.

Nestorian Doctrine espoused by Nestorius, archbishop of Constantinople, that Christ and God the Father are two separate entities. Nestorianism was to become a prominent version of Christianity spread along the Silk Roads and into China in Late Antiquity.

New Economic Policy (Russia) Established in 1921 by Vladimir Lenin, the New Economic Policy reconstructed some of the basic characteristics of capitalism with changes in the role of the Russian government. The policy, viewed as transitional, allowed peasants to sell their own produce and even own their own businesses, provided that they had fewer than 20 employees. Meanwhile, the government owned and controlled all banking and large industry.

Noble Eightfold Path The fourth of Buddhism's Four Noble Truths, focusing on wisdom, ethical conduct, and concentration as a means to attain enlightenment. *See also* Four Noble Truths.

Noh theater Noh is a form of theater developed in Japan in the fourteenth century. Noh plays fit two general categories: realistic or fantastic. Plays can center on the doings of gods, warriors, women, or the insane as well as on demons and other supernatural characters. Noh plays are performed on a square

platform covered with a temple-style roof. The sets, although minimal, include a bridge, and crossings represent journeys, often to and from the spirit realm. The actors, always men wearing masks, speak in a highly stylized form, with every gesture governed by tradition. They act to a musical accompaniment provided by a four-person orchestra, and a chorus provides ongoing commentary on the action, similar to the chorus in Greek drama. The related genre of Kyogen often features tales of heroes and a variety of broad comedies. Because Noh plays are not very long, performances can consist of several plays being performed one after another.

Nonaligned movement A movement initiated by many Third World nations during the 1950s and 1960s as an attempt to steer a course of neutrality between the United States and the Soviet Union in the atmosphere of the Cold War. These countries felt that they had nothing to gain from entering direct alliances with either of the two superpowers, although they frequently courted both sides in attempts to gain greater amounts of economic and military assistance. The nonaligned movement first met at the Bandung Conference in Indonesia in 1955. International meetings were held periodically over the next two decades, but the neutral nations were never able to formulate any cohesive policies because of the wide variety of member countries. With the end of the Cold War, the nonaligned movement lost any importance that it once held in international affairs.

Nongovernmental organization (NGO) Not-for-profit groups that are financially and politically independent of any nation or international organization. The core feature of all NGOs is that they exist to meet a human need that their members and supporters believe is not met by government or business. Especially in areas such as environmental issues, human rights, refugees, nutrition, and economic development, NGOs exert enormous influence in developing policy and managing programs. Some well-known NGOs are the Red Cross, the Red Crescent, Amnesty International, and Greenpeace.

Northwest Passage A mythical sea route across or around North America from the Atlantic Ocean to the Pacific Ocean. From the moment that the existence of a New World became known in Europe, European explorers hoped to discover such a route, seeking a relatively short passage to the East Indies and the rest of Asia. Many explorers tried in vain to find the Northwest Passage through the mid-nineteenth century. Only in the late nineteenth century was a route discovered that enabled ships to reach Asia by sailing through the Arctic Ocean, but it is commercially impractical because of severe weather. Global warming, however, appears to have improved access to this passage in recent years.

Nubia The region south of Egypt in which the powerful kingdom of Kush formed in ancient times.

O

Obsidian A natural volcanic glass that was often used for making cutting tools and weapons in prehistoric times. Its cutting edge was superior to that of flint and other stones and was prized by the peoples of prehistoric Eurasia and preconquest Americas for use in tools, ornaments, and ritual displays of status and wealth. Archaeologists are able to distinguish where obsidian pieces originated and thus can trace the trading of prehistoric people.

Oceania The name given to the islands of the Pacific Rim, a geographical construct inclusive of Australia, New Zealand, Micronesia, Melanesia, and Polynesia and part of the Malay Peninsula.

Oligarchy Form of government in which power is vested in an elite or aristocratic few, usually powerful families. In modern usage, the term assumes that rule is based on the elite's own interests rather than on the public good.

Ontology The philosophical quest to define the essence or nature of being, or existence itself; largely associated with Aristotle and the Platonic schools of thought.

Orthodox A set of views, particularly in religious context, that are in accordance with views authoritatively approved as the true, valid, and correct interpretation or set of standards, beliefs, or commandments. Orthodoxy can only be established after a source of authority, such as a church council, has been formed and authorized to create a formalized sanction of belief or opinion.

P

Pacifism An attitude of opposition to violence or war as a means of resolving disputes.

Paleoanthropology A branch of anthropology that includes the study of human and primate evolution, prehistory, and the biological and geological backgrounds necessary to their study. Paleoanthropology uses such techniques and skills as the study of fossils, evolution theory, dating through study of rock layers and other methods, and the review of technology used by different groups during different periods of their development.

Pan-Islamism A political idea that advocated the union of all Muslim peoples. Pan-Islamism first appeared in the Treaty of Kuchuk-Kainardji (1774), when Ottoman sultan Abdulhamid I claimed religious jurisdiction over Muslims living outside of his territories. As the Ottoman empire lost power and watched many Muslim states become absorbed by European nations, Abdulhamid used Pan-Islamism as a diplomatic tool, threatening to stir up unrest among Muslims should he be pressed too hard into unsatisfactory concessions. Within the empire, the idea of Pan-Islamism was used to rally Muslim patriotism.

Pantheism A monistic, as opposed to dualistic, religious view holding that God is essentially identical to nature and the material universe rather than above or beyond it, as the dualistic doctrine of theism holds. In other words, for pantheists the divine, rather than being totally transcendent to the world, is entirely within it, thus dissolving the split between God and world. Seventeenth-century pantheism was most developed by the German Lutheran mystic Jakob Boehme and the Dutch Jewish philosopher Baruch Spinoza.

Papyrus A type of reed, the paper made from its stems, or a scroll formed from sheets of the paper. The ancient Egyptians used the papyrus plant to make several things, including cloth, but it was primarily used to make paper. The Greeks and Romans also used papyrus paper.

Paradigm Refers to the typical example or model of something, often an idea. In recent years the term was popularized by physicist and historian of science Thomas S. Kuhn to describe a deeply held belief or assumption within a field of science that underpins general thought or research programs that depend upon a particular vision of the nature of reality.

Pasha/pasa The rank or title accorded to high civil or military officials (not religious leaders) in the Ottoman empire. The term "pasha" (*pasa* in Turkish) followed a person's name, as in Mustafa Kemal Pasha. During the period of the Tanzimat reforms, the term "pasha" was applied to the four highest classes of civil and military authorities.

Pastoralism Lifeways associated with nomads or groups that migrated in search of pasture land for their domesticated herds.

Patrilineal The practice of tracing descent through male lines that generally also involves passing family names and property through male bloodlines.

Peasant A member of an agricultural class who depends on subsistence farming, whether as a tenant or freeholder of a small plot. The classification effectively distinguishes an aristocratic landholder from an agricultural laborer.

Peonage A system requiring that debtors (generally peasants involved in agricultural production) repay debts to landowners through labor. The system was often in practice in the Spanish empire.

People of color Broad term sometimes used in the United States to describe all persons who are not whites of European descent.

Pilgrimage The experience of pilgrimage is common to all religions. Pilgrimage combines the quest for inspiration, blessing, or grace with the rigors of a demanding journey, a sacrifice made to God. A pilgrimage can be made to fulfill a promise, to plead for a cure or other favors, or simply to seek out a place imbued with the sacred. The journey itself is as important as the goal because it is a symbol of purification.

Plantation An English word used to describe the large commercial agricultural activities such as practiced by the Roman *latifundias* and later found in tropical or subtropical areas, the profitability of which is dependent on inexpensive or slave labor. The term is also used to describe settlements of people from imperialistic societies established in colonized areas, such as the English Protestant settlements (plantations) in Ireland.

Pogrom The word “pogrom” is derived from the Russian word for “havoc” and refers to the organized massacre or persecution of a minority group, usually used in reference to Jews. The first wave of pogroms followed the assassination of Russian tsar Alexander II in 1881 and lasted through the 1880s. A second wave occurred in the early twentieth century. The pogroms erupted and remained concentrated in southern Russia, though they spread to other areas like Warsaw and Novgorod. The Russian government sponsored some pogroms, ignored others, and passed laws limiting the educational, occupational, and residential mobility of Jews. Hundreds of Jews lost their lives, and many more had their property destroyed during the first wave of pogroms, which played an important role in crystallizing Zionism as a national movement and inspiring many Jews in Russia and eastern Europe to emigrate to the Americas and Palestine.

Polity An empire, state, or any form of its subordinate political structures such as counties, cities, districts, or any civil order that performs a governing role. The word derives from “polis,” the Greek term for city-states and the territories they controlled.

Polygamy A type of marriage in which a person is married to more than one spouse of the opposite gender. There are two types of polygamy. Polyandry describes marriage to more than one man, and polygyny is marriage to more than one woman. Polygyny, which was once common in most parts of the world, has become synonymous with polygamy.

Pope The bishop of Rome and the head of the Roman Catholic Church. Catholics believe the pope to be the successor to Saint Peter as well as Jesus of Nazareth’s vicar in the temporal world. The term “pope” itself derives from the word “papa,” or father. In late antiquity the term “papa” was used to designate respected religious leaders, regardless of their official rank. In the ninth

century that term came to be applied specifically and uniquely in the West to the bishop of Rome. In the early Middle Ages a succession of popes struggled with kings and nobles for control of local religious institutions. By the twelfth century the pope was not only the spiritual leader of the Catholic Church but also an important player in European politics.

Popol Vuh A document containing information on Quiché Maya culture and mythology considered to preserve the Quiché people's history, creation story, and myths.

Popular culture The culture of the "common" people. In previous centuries, much of the surviving cultural expression was often that of elite groups, and much is difficult to recover. In the twentieth century, new media led the way to a tremendous increase in cultural forms designed for a mass audience such as comic books, sheet music, Hollywood and Bollywood films, radio and television series, spectator sports, and popular music. Popular culture has become the subject of serious analysis as a medium from which to draw cultural inferences.

Porfiriato The name given to the period in Mexican history in which Porfirio Díaz (1830–1915) dominated politics.

Positivism A strain of liberal philosophy developed during the nineteenth century in England and France, positivism argued that empirical science was the only means of validating genuine knowledge. Its adherents believed that the pursuit of science guaranteed the steady progress of humanity. Those who wished to undermine the importance of theology found positivist ideas particularly useful, and positivism was very popular in Latin America among liberal government leaders who sought to reduce the power of the Catholic Church. Among the best-known positivist thinkers were Auguste Comte of France and John Stuart Mill of Great Britain.

Postcolonial Term used to describe cultural, political, or economic changes in new states after the process of decolonization and their new relationship to the developed world/former colonizers.

Predestination A theological view adopted by John Calvin (1509–1564), holding that God exists outside of the limits of time and is infallibly prescient about all things, past and present, knowing the origins and outcomes of all events in history, including all aspects of individuals' lives and ultimate salvation or damnation.

Prefecture The largest governmental unit in Japan, followed by cities, towns, and villages. Japan is divided into 47 prefectures, which are administered by governors and assemblies. The size of the prefectures range from Hokkaido, the largest prefecture at more than 32,000 square miles (82,880 square kilometers), to Osaka, the smallest prefecture at 720 square miles (1,865 square kilometers). Tokyo is the only prefecture designated as a metropolitan prefecture, and it is the most populous. Governors of the prefectures are elected by local residents.

Primogeniture The right of the oldest son to inherit all of the family estate, regardless of whether there are any other heirs. The origins of the practice lie in the deep past and have the merit of ensuring an orderly transmission of property and rank, enabling a family to maintain its position and wealth.

Privateering The raiding of enemy commerce by privately armed vessels licensed by letters of marque (formal documents authorizing private individuals to seize the goods of enemy states) for strategic reasons. As one example, the sixteenth-century privateer Sir Francis Drake captured a prize so large in 1577 that Queen Elizabeth I was able to retire the national debt with the Crown's

share. Understandably, he was regarded as a hero in Britain (where he was knighted) and as a villain in Spain (whose ships he looted and sunk).

Privatization The act of transferring companies, industries, assets, or resources from government to private entities, such as individuals or corporations.

Propaganda A type of communication developed for the purpose of influencing the perceptions or views of those toward whom it is directed. Since World War II the perceptions of propaganda have been largely negative, but the mode of communication has also been used effectively to influence health and safety issues.

Protectionism A government policy that attempts to protect a nation's domestic industries from foreign competition. Such restrictions as tariffs, subsidies, and import quotas are used to block or decrease the import of goods that can be produced domestically. The mercantilist policies of European monarchs in the seventeenth and eighteenth centuries were based in protectionism. The most famous example of protectionism in the nineteenth century was Great Britain's Corn Laws, which depended on import tariffs to make imported grains more expensive than those domestically produced.

Protectorate The term used to describe the period in British history when England was ruled by the lord protector, Oliver Cromwell (1653–1659). In recent history, the term “protectorate” describes the circumstances when a developing state is put under the protection of a hegemonic power, sometimes as a precursor to attempts at colonization.

Ptolemaic The Egyptian kingdom founded by Alexander the Great's general, Ptolemy. The term also can refer to the thought of Ptolemy of Alexandria, a philosopher who championed the mathematical consistency of an earth-centered solar system, later challenged during the Copernican revolution.

Public education Educational systems, usually free of cost, as instituted by republican and constitutional states worldwide that grew from industrializing societies' recognition of their need for literate workers, having the dual purpose of instilling national and cultural values.

Public health movement The public health movement gained popularity in the late nineteenth century and was primarily concerned with preventative treatments, prenatal care, and pediatric services. The first European clinics appeared in Paris and Barcelona (1890) and London (1899). In the United States, the first strong public health movement resulted in the founding of the National Association for the Study and Prevention of Tuberculosis in 1904. Public health clinics generally receive funding from both public and charitable sources.

Purdah/pardah The practice instituted by Muslims and later adopted by some Hindu groups of keeping women isolated from public observation by requiring concealing clothing and veils when they are outside their homes. Within the home, curtains and enclosures are used to keep women out of sight.

Q

Qin dynasty The Qin dynasty ruled China for a short time, during 221–207 BCE, but instituted many of the practices that allowed the Han dynasty to form a strong state, including standardized currency, writing, and measurements. The Qin constructed many miles of roads and waterways, including the Grand Canal linking northern and southern China. The dynasty came to rule via conquest. Its founder, Qin Shi Huangdi, was a violent and paranoid man who

declared himself “the First Emperor” and set the stage for a modern government when he ignored the nobility and ruled through a centralized structure.

Qing The dynastic name assumed by the Manchus, a group from northwestern Asia that assumed power after Chinese rebels had overthrown the Ming dynasty. The Qing ruled China during 1644–1911 and brought China to an apex of wealth and power in the mid-eighteenth century before being humiliated by the British in the Opium Wars (1839–1842, 1856–1860). The Qing never recovered but endured until 1911.

Qizilbash Ottoman Turkish for “redheads.” The Qizilbash were members of seven Turkmen tribes in Iran who supported the founders of the Safavid dynasty. Military warriors from the late thirteenth century onward, they were key in the transformation of the Safavid empire from a religious to a political state. In return for fighting for the shahs, members of the Qizilbash were rewarded with administrative privileges. However, feuding among the Qizilbash eventually led to their demise during the rule of Shah Abbas I. The name was later applied to Shia Muslims in eastern Asia Minor and Turkmen in Afghanistan.

Quetzalcoatl The “feathered serpent,” a god and patron of creation, learning, and knowledge. Quetzalcoatl has been associated (under various names) with Mesoamerican societies for more than 1,000 years and was important in Toltec, Maya, and Aztec religious views. There is some indication that the veneration of the god traveled up the turquoise trail to the Anasazi people, the probable ancestors of the Hopi and Zuni tribes of the southwestern United States.

Quipu Derived from the Quechua word *quipu*, meaning “knot.” An apparatus of colored cords tied in knots that were used as a record-keeping system by the ancient Incas.

Quran Sometimes spelled “Koran,” the Quran is the holy scripture of Islam. It records the teachings based on the revelations sent down from Allah to the Prophet Muhammad during 610–632. Muhammad’s utterances were collected and ordered into a book sometime after his death. Regarded among Muslims as the word of God himself, the Quran provides a guide for social and personal life and details the religious responsibilities of Muslims. The Quran is one of the most influential texts in human history.

R

Racism Prejudice or discrimination based on the assumption that certain races possess superior mental and/or physical capacities. Racists believe in their own racial superiority even though there is no scientific proof that any racialization exists in humans. In fact, most modern anthropologists and geneticists reject the idea that humans can be divided into distinct racial categories at all. Since the mid-nineteenth century, racism has led to the oppression, enslavement, and sometimes even the attempted extermination of one group by another. Many scholars consider racism to be a modern expression of tribalism.

Radicalism Extremist ideological and/or political movements on both right- and left-wing fringes seeking change; adherents often espouse violence.

Radiocarbon dating Method that archaeologists use to date the origin of documents and artifacts that relies on measurements of the presence of carbon isotopes in organic matter, the levels of which begin to decrease once life ends.

Raj The Hindu word for “rule.” In English, Raj refers to the period of British rule over India. The British East India Company established British control

over important Indian harbors in the seventeenth century, and the company administered the colony as it continued to acquire more territory. As a result of the Indian Rebellion of 1857, better known as the Sepoy Mutiny, the British Crown liquidated the East India Company in 1858 and directly administered the colony until the end of the Raj in 1947, when India achieved independence.

Rajput Hindu Kshatriy soldiers and landowners in India who were the primary obstacle to Muslim domination of India beginning in the fourteenth century. Their dynasties ruled much of northern India, and they managed to retain their independence until the Rajput Rana Sanga was defeated by the Mughal emperor Babur at the Battle of Khanua in 1527. The Rajputs accepted overlordship by the Mughals under Akbar and served in various positions of government until the collapse of the Mughal empire in the eighteenth century.

Ramadan The ninth month of the Muslim calendar when it is believed that the Quran was sent to Mohammad. Observance of daytime fasting during this month is one of the required devotional acts of the Five Pillars of Islam.

Ramayana Ancient Hindu epic text recounting the life story of Prince Rama of Ayodhya. Rama was later deified as an incarnation of the Hindu god Vishnu. The epic is still retold in recitations at yearly festivals and in folk songs, films, and television series.

Rationalism The philosophical outlook that evolved out of the thinking of several seventeenth-century and eighteenth-century European philosophers. Rationalism was characterized by its claim that certain knowledge of the natural world was available to humans solely through the mind's reasoning ability. Rationalism arose in large part in response to earlier philosophical and theological methods that described the world primarily through personal experience and faith. For many Enlightenment rationalists, it was human reasoning that implied the existence of a God.

Re An ancient Egyptian solar deity (also spelled "Ra"). Re's association with the sun meant that he was understood to be an important force in the creation of the world, and Re's daily movement (from sunrise to sunset) was an embodiment of the cosmic order. *See also* Amun-Re.

Recession An economic downward trend in the business cycle characterized by a general decline in production and investment, increased unemployment, and lowered income and spending by individual households.

Refugee An individual forced to flee from her or his home country due to persecution, warfare, economics, or environmental disaster.

Relic The physical remains of a saint or objects that were touched by a saint. In Buddhism, Islam, and the Catholic Church, relics are given great reverence, and miracles are said to occur in their presence. The Catholic Church affirmed the importance of relics at the Council of Trent in 1563 and established rules to confirm their authenticity. Most relics are associated with a religion's founder or primary leaders, such as the shrines erected throughout Asia that are said to hold the remains and possessions of the Buddha.

Repatriamiento Labor system established by Spanish colonial authorities in the Americas whereby indigenous communities were required to provide labor for Spanish landowners in exchange for wages.

Republic A form of government in which sovereign power resides in the citizenry and is exercised by elected representatives who are responsible to the people. Republican government stands in contradistinction to monarchical or oligarchical government, in which the rulers have a vested right to office. A republic is also to be distinguished from a pure democracy, in which

the people govern directly. In the century following the American Revolution and the French Revolution, republican government emerged in many countries to replace monarchical systems.

Republicanism A political philosophy that gained support beginning in the eighteenth century in which elected officials represent the interests of citizens who desire a limited government role in economic and social life. The theory of republicanism also included the notion that citizens had to remain virtuous and educated for a republic to succeed and avoid corruption. In the United States the republican credo as expressed by Thomas Jefferson included a great suspicion of urban life and a championing of the notion of the independent farmer as a repository of virtue.

Revolution An internal political uprising that attempts to establish a new political order, usually with the support of a significant proportion of the population. A revolution is distinguished from a coup d'état, which is a brief and swift seizure of power that may in fact occur as part of a broader revolution. Revolutions are often associated with a shift in political ideology rather than a sheer desire for power and seek drastic social or political change.

Romanticism One of the major intellectual movements of the late eighteenth and early nineteenth centuries in Europe and North America, Romanticism refers to a movement in literature, music, and the visual arts that rejected rationalism and exalted the subjective, emotional and transcendental aspects of life. The effects of Romanticism were carried over into politics through its emphasis on individual freedom, heroism, and political justice for all people.

Ronin Masterless, landless samurai in seventeenth-century and nineteenth-century Japan. Prior to and after the founding of the Tokugawa shogunate in 1603, large numbers of ronin roamed Japan causing trouble, having either lost their masters through death or been disposed of for bad behavior or losses in battle. In the nineteenth century the ronin took up the cause of expelling Western influence from Japan and restoring the monarchy. Many samurai left their masters and became ronin to engage in a campaign of assassinations and disruption. The Meiji government's abolition of samurai privileges brought an end to the ronin in 1873.

S

Salon In Europe, particularly France, and the Americas during the eighteenth century, salons were held in the homes of private individuals and served as gathering places for the socially prominent to discuss intellectual trends and science with philosophers associated with Enlightenment thought. The women who organized and hosted the salons exercised considerable social power in their sponsorship of certain guests and helped shape the age's intellectual currents.

Sanitation Revolution Mid-nineteenth-century movement in Europe and the Americas to ensure public health with the institution of health care and sanitation measures, particularly in urban centers. As with other reform movements, the Sanitation Revolution represented the middle- and upper-class evangelical outlook. Not just communities but also individuals (particularly the poor) and their habits were targeted for reform.

Sanskrit An ancient Indo-European language preserved today through Indian classical literature and texts. Sanskrit is an official language of India and is one of the oldest surviving branches of the Indo-European language family,

which includes Latin, Greek, English, and the majority of modern European languages. The oldest surviving Sanskrit texts are the Vedas, sacred Hindu texts that date from the second millennium BCE. The term “Sanskrit” means “completed” or “perfected,” referring to the Hindu belief that the language was refined over a long period of time to become perfect. Sanskrit was deeply influential in the development of modern Indian languages. Knowledge of Sanskrit has long been considered a mark of distinction and education in Hindu society.

Satrap A provincial governor in the Persian empire and its successor states who had both military and political responsibilities. The word “satrap” is derived from Persian for “protector of the kingdom.” The title of satrap first appeared during the rule of King Darius I of Persia to describe his representatives in two provinces. The title was later applied to other imperial representatives. Because some provinces were controlled by governors, the term “satrap” implied royal favor and special social status. The court maintained by a satrap was a minor version of the imperial court, with the satrap enjoying a great deal of autonomy.

Savanna An area of dry grassland sparsely dotted with short trees. The climate is generally hot but includes both dry and rainy seasons. Many species of wild animals make their habitats in savannas. The savanna of western Africa historically has been an important region for the development of ancient civilizations. Its geographical location made it strategically important for trade routes to and from North Africa, where the Egyptians, the Romans, and other peoples had built empires. Some of the most important ancient civilizations of the African savanna included the Mali empire and Ghana.

Scholasticism A particular Christian philosophical mode and style closely associated with Thomas Aquinas (1224–1274) that arose in the medieval universities of Europe as Christian thinkers attempted to reconcile and fuse Aristotelian philosophy with Christian theologies. Many of these Christian thinkers sought to solve general philosophical problems dealing with a combination of faith, reason, will, and intellect.

Scientific method Formulated by thinkers such as Francis Bacon in the seventeenth century, the scientific method is a process that scientists use to construct accurate theories about the world. There are four steps in the scientific method: observation and description of a phenomenon, formulation of a hypothesis to explain the phenomenon, use of the hypothesis to predict other phenomena, and experiments to test the predictions. Prior to the development of the scientific method in the seventeenth century, dogmatic assertions about the universe were often taken as matters of fact and faith.

Second World Term used during the Cold War in reference to Soviet-dominated Communist Bloc states. *See also* First World, Third World.

Secularization The process through which a society becomes more concerned with temporal, material, and ethical issues than with spiritual and religious matters. The eighteenth-century European period known as the Enlightenment is an excellent example of an intellectual movement toward secularization as people began looking to human reason, science, and nature for the solutions to problems rather than depending on piety, religious texts, and prayer.

Sedentarism Anthropological term for describing a people who lived in a fixed village or town rather than being nomadic or migratory.

Self-determination Theories of self-determination propose that any society is comprised of a people having the right to decide on their own political affiliation without the outside influence of other people, groups, or institutions.

Separate spheres The concept of separate spheres, based on the physical and presumed essential differences between men and women, dominated thinking about gender roles throughout much of the nineteenth century. According to this ideology, women's proper sphere of activity is in the home and family as wives, mothers, and transmitters of virtue. The public sphere was meant for men. This concept has historically been used to legitimize gender-based laws.

Sepoys The northern Indian peasant warriors who had been mercenary soldiers from the 1450s. Both the British and French hired sepoys at times. By the mid-nineteenth century sepoys constituted approximately four-fifths of the British army in India.

Serf A peasant bound to the land, common to the Roman empire, ancient China beginning in the Han dynasty, and Europe in the Middle Ages. During the Roman empire, serfs were commonly known as *coloni*, or tenant farmers. Similar to medieval serfs, *coloni* ran their own farms and bore all its successes or failures. During the late Han dynasty a client-status developed that wedded serfs to an estate owner's property. In Europe, serfs could not own land and were tenants on manors or large estates. On some manors, lords might demand up to five days of labor per week from a serf. Serfs also owed the lord other such duties as a gift of his best livestock when he died. Serfs were not allowed to leave the manor, marry, or go to school without the lord's permission. By the sixteenth century serfdom was ending in England and France along with the growth of a money economy. Serfdom persisted longer in eastern Europe.

Serfdom A condition of bondage. In medieval Europe, serfs worked the land of their feudal lords and submitted to other arbitrary obligations in exchange for military protection. With the rise of commerce and central government in most of western Europe, most serfs acquired freedom of movement and, with certain restrictions, the right to own and dispose of private property. In Poland and the Holy Roman Empire, where weak monarchies left many governmental functions to the nobles, the institution of serfdom became more stringent during the seventeenth century. In Russia, on the other hand, where a free peasantry had been traditional, the labor requirements of seventeenth-century nobles led to a form of serfdom that resembled the plantation slavery of the Americas.

Sexuality The quality of being concerned with or characterized by sex or sexual activity, possessing sexual power or potency. In academic writing "sexuality" is used as an umbrella term to refer to cultural or individual expression related to gender roles as well as sexual practices, beliefs, preferences, or norms characterized by biological as well as historical and cultural influences.

Shah The title given to kings in Persia and present-day Iran. The title of shah is also used by rulers in southern and central Asia, such as in Afghanistan prior to the overthrow of the monarchy in 1973. Hereditary rulers and heads of Sufi orders often incorporated the term "shah" into their names, like Fath Ali Shah, the second shah of the Qajar dynasty.

Sharia The Islamic code of laws based on the Quran, Muhammad's life, and examples from Islam's early days. Sharia was drawn up by Muslim scholars after the death of Muhammad to provide Muslims with a practical guide to daily life. All Muslims are expected to lead their lives according to the sharia, much of which is based on the Quran. The sharia includes guidelines for penal law, laws of transactions, family law, succession law, and court procedures and is traditionally administered by sharia courts.

Shia One of the two major branches of Islam. In contrast to Sunnism, Shia believe that the prophet Muhammad designated a successor—his son-in-law

Ali—and that Ali's descendants are the only rightful Islamic leaders. The Shia tradition emerged in opposition to the political dominance of Sunnism in most areas, although there have been exceptions to that rule, notably in Persia where the Safavid empire established Shia as the religion of state. Shia is sometimes referred to as Shiism.

Shiism *See* Shia.

Shintoism Indigenous Japanese religion that pays homage to spiritual entities called kamis, believed to reside in sacred spots such as boulders, trees, or rivers, as well as deified humans or emperors. Shintoism adapted to the arrival of Buddhism in Japan, and many Buddhist temple grounds include Shinto shrines. As part of the Meiji Restoration of the mid to late nineteenth century, Shinto was temporarily severed from Buddhism and tied to nationalism, centralized power, and a cult of the emperor.

Shogun The title of the highest military officers, who ruled Japan from the twelfth century through the nineteenth century after power was wrested from the imperial house. In the Tokugawa period (1600–1867) the shogun ruled a unified Japan from a capital in Edo (present-day Tokyo). The Tokugawa shoguns remained in power until the Meiji Restoration in 1868.

Sikhs Members of an Indian monotheistic religion, which they call Gurmat (Punjabi for “the Way of the Guru”) established in the Punjab area of northern India by Guru Nanak (1469–1539). Sikhism clearly began in the Hindu tradition, but some scholars have noted an Islamic influence as well. Sikhs were noted for their military expertise in the nineteenth century.

Silk Roads/Silk Road Trade routes that crossed central Asia via land and sea, linking China to Syria, South Asia, and the eastern reaches of the Roman empire. The Silk Roads were critical to the prominence of the civilizations of China, India, and Rome.

Slav The largest ethnic and linguistic group in Europe. The largest Slavic groups live in eastern and southeastern Europe in nations that were once part of the Soviet Union, including Russia, Ukraine, Belarus, Poland, the Czech Republic, Slovenia, Serbia, Croatia, and Macedonia. Traditionally there has been little unity among the various Slavic people. Western Slavs were influenced by Western ideas, are associated with the Catholic Church, and use a Latin alphabet. Eastern Slavs were more isolated, are associated with the Eastern Orthodox Church, and use a Cyrillic alphabet. A Pan-Slavism movement in the eighteenth century attempted to unite all Slavic peoples under the leadership of Russia, a dream somewhat achieved after World War II when many Slavic peoples became part of the Soviet Union. Most attempts at unity have been disastrous, however, as evidenced by the Yugoslavian Civil War of the 1990s.

Social Darwinism Social theory promoted by various Victorians, particularly Herbert Spenser, postulating that “survival of the fittest” (a phrase first used by Spenser) worked in human societies as well as in the development of living organisms. The notion was used in the late nineteenth century and the early twentieth century to justify widening class gaps, imperialism, and laissez-faire economic and political policies. It should be noted that Charles Darwin never proposed extending notions of evolution to social organization.

Socialism Political and economic theory that gained popularity in the early nineteenth century with the rise of industrialism that argues for the collective ownership or at least the fair distribution of resources, especially the means of production. Communism is a branch of socialism that postulates that violent revolutions are often necessitated to achieve socialist goals. There are many variants of socialist theory.

Soteriology The branch of Christian theology that focuses on doctrines and ideas that relate to salvation.

Soviet The Russian name for a number of committees or councils with executive and other functions. The term “soviet” was used for many revolutionary councils prior to the revolution. The Bolsheviks depended on the Soviets as a source of their gathering power during the Revolution of 1917. Following the revolution the name “Soviet” was applied to local and regional legislative bodies; however, their autonomy was delimited by central party decisions. The term was also used for citizens of the USSR.

Stele/stela An upright inscribed stone slab or pillar used as a monument, boundary marker, or gravestone that can feature art, writing, or a combination of the two or be left uninscribed. Common throughout the Near East and Mediterranean, the use of stelae also developed independently in East Asia and in Mesoamerica, particularly among the Maya. Some of the more famous stelae include inscriptions detailing the Code of Hammurabi and the Lhasa rdo-ring (Long Stone of Lhasa) in Tibet, which dates from the early ninth century CE.

Steppe A vast flat expanse of semiarid grassland in central Asia. The steppe has been the home of nomadic herders throughout history.

Subinfeudation The practice whereby a vassal created vassals of his own from the tenants on his lord’s divided estate. The vassal then became a lord himself. In the medieval system of feudalism, a lord granted his vassal land and protection in return for military service and certain other such obligations as hosting the lord and his retinue when he visited. A vassal might also serve at the lord’s castle, serve as a juror, or help ransom the lord if he was captured.

Suffrage The right to vote. In the eighteenth and nineteenth centuries, most countries based suffrage on such special qualifications as land ownership or literacy and limited suffrage to certain racial or ethnic groups. Today most modern governments provide for universal adult suffrage, regarding it as a right that comes with citizenship. Suffrage that is not based on race or sex has often been a rallying cry of political movements throughout the world.

Sufi See Sufism.

Sufism The most mystical branch of Islam. Most Sufi sects sought a more personal relationship with God than that advocated by the more formal and legalistic approach of the ulema, the established Muslim scholars. Sufi practice was characterized by organization in brotherhoods (*tariqahs*) that followed the same path of worship and often venerated the tombs of local saints. Sufism remained very important in the far western (North Africa) and the far eastern (Indonesia and Southeast Asia) parts of the Muslim world, where the standardized practice of centralized states was not always available.

Sultan A king or sovereign, usually of an Islamic state. The title of “sultan” has been used in that regard since the eleventh century and in such countries as Iraq, the Ottoman empire, and Somalia.

Sumer The area in the southern half of Mesopotamia which was the home to approximately 30 early city-states built by a culturally cohesive but politically divided people, the Sumerians, who were among the first (if not actually the first) to develop complex political organization as well as writing, irrigation, etc.

Sunnism One of the two principal divisions of Islam, the other being Shia. Sunni Muslims base their legitimacy on the sayings and actions (or *sunna*) of the Prophet Muhammad. They believe that the leadership of Islam passed from Muhammad in the seventh century to the caliphs (or disciples) elected from Muhammad’s tribe. The sixteenth and seventeenth centuries were a time of

great expansion for the two great Sunni Muslim empires—the Ottoman empire and the Mughal empire—though that growth had slowed by the end of the seventeenth century.

Sura A chapter of the Quran. There are 114 numbered and named suras of varying lengths in the Quran. Each sura represents either the full content of one separate revelation delivered to Muhammad or a mixture of more than one revelation. The suras are labeled as either Meccan or Medinan; many scholars have interpreted that labeling to indicate whether the revelation came to Muhammad during his time in Mecca or in Medina.

Sati/suttee A Hindu practice in India in which a widow burned herself on the funeral pyre of her husband or set herself on fire shortly after his death. Occasionally a woman was burned before her husband entered battle in order to prevent her dishonor if he died; that practice was called *jaubar*. It was a common belief that men needed their wives in the afterlife, but sati may have spread because of the difficulties that widows faced in Hindu society. Stone memorials to such widows date back to the sixth century CE, but references to suttee are found in much older texts. For example, Diodorus Siculus, a Greek historian of the first century BCE, noted the practice in his description of the Punjab region of India.

Synagogue A Jewish religious and community center. Synagogues existed well before the third century BCE, and evolved as centers for public activities. Besides a central room for religious services, synagogues provided space for instruction for children, religious study for adults, and court proceedings. They also provided a home for a Jewish community's archives and library, a depository for funds, and lodging for travelers. Synagogues were especially important for Jews who relocated from Palestine during the Diaspora of the Hellenistic era, since they provided the only community framework available. Following the destruction of the Second Temple of Jerusalem in 70 CE, the religious role of synagogues became even more important.

Syndicalism Flourishing in the early twentieth century, syndicalism was a sociopolitical philosophy that advocated direct action by the working class to overthrow and dismantle the capitalist state. The philosophy was based on elements of both Marxism and anarchism and held that workers should unite in a series of strikes to overthrow the government, which was inherently corrupt and therefore incapable of reform. In place of the state, syndicalists hoped to establish small cooperative associations (syndicals) that functioned on the local level and coordinated themselves with other syndicals. Syndicalism lost influence after World War I and the Russian Revolution of 1917, when many revolutionaries threw their support behind Soviet communism.

T

Tanzimat reforms A series of measures that were intended to modernize Turkish education and law and put Ottoman society on a more equal footing with the Europeans in the mid-nineteenth century. By the early nineteenth century, the major powers of Europe were far ahead of the Ottoman Turks in science, mathematics, and other fields. Since this educational superiority had also led to European military advantages over the Ottomans, the Tanzimat reforms were enacted.

Tariff A tax levied on goods coming into a country, usually by the government of the importing country. Tariffs can raise money for the government and protect the domestic economy from an influx of cheaper foreign goods.

Temperance movements European and American social movements of the nineteenth and twentieth centuries advocating prohibition and the elimination of alcohol, which is seen as an agent promoting other social ills.

Theocracy Derived from the Greek meaning “rule by the deity.” A theocracy is a government that is directly operated by officials who claim divine appointment. They interpreted the law, the political context, and natural events in terms of the divine. Many ancient civilizations were governed by theocracies, including the Egyptians, Hebrews, Tibetans, Maya, Toltec, Aztecs, and Natchez.

Third World A term used in reference to the developing and or nonaligned countries in Africa, Asia, and Latin America in the context of the Cold War. It is assumed that these states have low literacy, low per capita income, and limited industrial capacity. The term “Third World” originated in Europe, but there is no clear consensus on its exact origin, which some attribute to the notion of the Third Estate of the French Revolution, that is, the nonelite. Be that as it may, the term “Third World” was in common use by the 1960s. The First World refers to the industrialized Western powers, including Western Europe, the United States, Canada, etc.; the Second World refers to the Communist Bloc, including Yugoslavia. *See also* First World, Nonaligned movement, Second World.

Torah Central texts in the religion of Judaism. Torah is the name commonly given to the first five books of the Bible, also called the Pentateuch, or Chumasch, that are said to be recorded by Moses straight from the words of God. The term “Torah” can also refer to the entire Hebrew Bible (or Tanakh), which is the Old Testament of the Christian Bible. In addition, the word “Torah” can mean the entire body of Jewish theology and teaching.

Trade deficit Occurs when an entity, generally a nation-state, buys more goods and services than it sells. Trade deficits are addressed in many ways, but the course of first choice is to develop an export product that would be in high demand, particularly in those states that are in a trade surplus situation. Trade deficits can also be addressed through import taxes and tariffs imposed that serve to raise the prices of foreign goods to amounts equal to or greater than those paid for goods produced.

Trade union An alliance of workers created to promote the interests of its members regarding wages, working conditions, and benefits through the process of collective bargaining with employers. Most trade unions are organized around the interests of one particular industry or a particular skill or craft. While the term “trade union” can be interchangeable with the term “labor union,” the term “labor union” can imply membership across trades and skill levels. The trade union movement developed in the early years of the nineteenth century and grew rapidly particularly in Great Britain after the repeal of the Combination Acts, which had prohibited workers from forming trade unions.

Trading bloc A group of nations that have entered into a free trade agreement. Most nations enter trading blocs in an attempt to provide higher-quality goods at lower prices to consumers in each of the countries. Poor countries that become members of trading blocs often receive large amounts of capital investments by wealthier countries. Examples of trading blocs include the European Union, the North American Free Trade Agreement (among Canada, the United States, and Mexico), Mercosur (among Argentina, Brazil, Uruguay, and Paraguay), and the Asian Free Trade Area, an outgrowth of the Association of Southeast Asian Nations.

Triangular trade Refers to patterns of oceanic trading ventures that required a round trip with three destinations. The best-known use of the triangle involved eighteenth-century trading ships from New England that carried rum and other goods to the west coast of Africa to be exchanged for slaves. The slaves then became the cargo for the voyage to the West Indies (the infamous Middle Passage), where they were exchanged for molasses to be transported back to New England and turned into rum.

Tributary state A tributary state maintains many or all of its autonomous institutions and practices but must pay a tribute to a hegemonic state, often (but not always) making some cultural concessions.

Trusts In the late nineteenth century, the heads of many large businesses tried to eliminate competition within an industry by forming trusts, a form of monopoly in which all shares of stock from participating companies were placed under the control of a single organizing body that held the stock in trust for the companies' owners. Trustees, who were usually bankers like J. P. Morgan, made decisions for the industry, setting prices and assigning spheres for each company and thus driving nontrust companies out of business and eliminating competition. The unfair practices of the trusts led to a public movement for business reform, culminating in the Sherman Antitrust Act (1890).

Tumulus A barrow or small earthen mound, often covering an ancient grave.

Twelver Shia A branch of Islam popularized by Shah Ismail in the Safavid empire that claimed there were 12 ideal religious leaders who had followed Muhammad and that the twelfth would someday emerge from hiding. Twelver Shia is also known as Twelver Shiism.

U

Ulama From the Arabic word for "learned." Ulama are Muslim scholars who are the main interpreters of Islamic law.

Upanishads A collection of Vedic and Hindu texts, primarily written between 800 and 400 BCE, that form the early canon for knowledge of Hindu principles and the understanding of the universe.

Urbanization In regard to ancient times, the term "urbanization" refers to the process by which cities became the center of political and economic life in a culture and to the concomitant physical growth of urban areas. Modern urbanization generally accompanies industrialization and the creation of new housing as well as transportation and communication infrastructure. Accelerated urbanization is often characterized by poor housing and sanitation conditions, leading to the poor hygiene and overall health of residents. Poverty perpetuated by low factory wages, insufficient diet, and other social ills, including alcoholism and violence, are frequent criticisms of modern urbanization.

Usury The practice of charging interest for money loaned. In present-day law, states sometimes regulate the rates of interest. During the European Middle Ages, all forms of interest were condemned as immoral, and sinful. Lending with any interest was prohibited to all Christians by canon law. During the twelfth and thirteenth centuries, Europeans were forced to reconsider the idea of charging interest: the commercial economy that accompanied the rise of towns could not function without loans, and people were not likely to make loans if they could not profit from them by charging interest. That problem was solved in part by creative arrangements borrowing heavily from the practices that migrated into Italy. Princes and monarchs were often able to force loans

from wealthy Jews, and often defaulted. By the sixteenth century, in many areas usury became defined more narrowly, as charging unfair or excessive interest, allowing lenders to realize some profit.

V

Vassal During the era of feudalism in the Middle Ages, a vassal was a person who pledged loyalty, homage, or fealty to a lord. Vassals performed such duties as military service in return for protection and a fief, an area of land that they governed on behalf of the lord.

Vedas Sanskrit texts dating to the second and first millennia BCE.

Vernacular A term used to describe cultural phenomena such as language, tradition, or architecture that are indigenous or native to a particular group or region. Vernacular styles, such as in architecture, can define particular regions, historical periods, and cultural influences.

Vizier A high government official or minister for the Egyptians, the Mongol empire, the Persian empire, Ottoman Turks, and other Eastern peoples. The English word “vizier” comes through Turkish from the Arabic *wazir*, which meant “caliph’s chief counselor.” In ancient Egypt, a vizier was a governmental official ranked directly below the pharaoh; the Egyptian word for such an official was *tjaty*. The term was also used for officials in some Muslim countries, especially during the Abbasid dynasty and the Ottoman empire, as well as in the Middle Ages and the early modern era.

W

Waterpower From ancient times through the early industrial revolution, water was one of the main sources of power for construction, milling, and other basic industries.

Westernization The process of adopting political, social, and economic practices that originated in Europe and the United States. In the eighteenth and nineteenth centuries, Westernization became synonymous with industrialization efforts in Japan, Turkey, Russia, and other parts of the world as underdeveloped nations attempted to implement technological and institutional innovations. Charismatic leaders such as Russia’s Peter I introduced Western-style education, fashion, military, and industrial practices. Such efforts were often met with resistance; however, at the same time indigenous nationalists might push for Westernization as a strategy for gaining national power, as in Meiji Japan.

World system/systems Controversial neo-Marxist theory of world history developed by sociologist Immanuel Wallerstein that describes how a world economy depends on a hierarchy of core, semiperiphery, periphery, and external regions of varying economic influence. Colonialism and neocolonialism, for example, both depend on a relation between a dominant core and a subordinate semiperiphery and periphery from which core regions might draw resources or find markets. Other scholars, such as Andre Gunder Frank and Janet Abu-Lugod, have further refined the concept. Critics point to the growing power of India and China, which once would have been considered peripheral states, as evidence that any world economic system would necessarily be more fluid and mutable than Wallerstein portrayed.

X

Xenophobia The fear of foreigners that may underlie cultural interactions as well as international and national politics.

Y

YBP Meaning “years before present” and sometimes simply referred to as BP (before present), YBP is a term used by archaeologists to define historical events. The year 1950 is set as the “present” for such time measurements.

Z

Zen Buddhism An offshoot of Buddhism that focuses on an individual’s achievement of enlightenment and de-emphasizes religious dogma. Zen Buddhism stresses the importance of Zen masters in helping followers (students) achieve enlightenment through such practices as meditation and pondering riddles. This form of Buddhism (known as Chan Buddhism) was dominant in China by the ninth century and spread to Korea and then to Japan as early as the fourteenth century, where it became known as Zen.

Zionism Political movement advocating the establishment, expansion, and preservation of a Jewish state in Palestine.

Zoroastrianism A dualistic, probably ancient, Indo-European religion that revived in Persia with the teachings of the prophet Zarathustra, the earliest known theologian, who probably lived in the sixth century BCE. He recognized a supreme deity, the creator of all goodness and light, but also an independent foe, Angra Mainyu or Ahriman, the great deceiver and author of all lies and other evil. Zarathustra taught that at the end of time, Ahura Mazda, supported by good humans, would prevail after a huge battle. Individual humans would then be judged and would receive rewards for good acts or punishments for evil done. Zoroastrian priests were called Magi and played a role in the nativity stories of Christianity.

ERA 1 Beginnings of Human Society to 4000 BCE

This volume is concerned with the biological evolution of our species—*Homo sapiens*—as well as the origins of the social, political, and economic institutions that have characterized our cultural evolution. Although the contributions in this volume are in one sense broadly historical in that they describe our past, they have been informed by very different methods, approaches, and intellectual traditions than those commonly thought of as history. Archaeology, paleontology and paleo-anthropology, geology, studies of ancient climates, molecular genetics, physics, and linguistics have been brought to bear on the development of a more comprehensive understanding of the early history of our species. Indeed, evidence from written language, the standard means by which historians create reconstructions of the past, can barely be found in the pages of this volume. Writing such as we understand it appears fairly late in our cultural evolution, and even then, much of what was written down by cultures, such as those in the ancient Middle East, for example, was more about keeping track of economic transactions than describing the events, peoples, and politics of times past. This era, then, sees little traditional historical narrative and analysis.

Instead, the contributions to this volume are best seen as prehistory, which can be defined as the study of the past through the material remains created and left behind in burials, trash deposits, structures, and monuments by individuals, societies, and cultures. Archaeology is the primary means by which these material remains are recovered. Archaeologists identify important sites, excavate them, and examine the objects to create explanations about what happened in the past. And as noted above, data from other sciences are used to develop a more comprehensive picture of the past whenever this is possible.

This volume has adopted a global perspective, one that is best described as world prehistory. Although global in scope, this approach is at once regional (what was village life like in ancient China 8,000 years ago?) as well as comparative (when do we see the first villages in the ancient Near East and how do they compare in size, social organization, and complexity to the earliest villages found in other parts of the world?). This allows us to observe similarities and differences in the pace of cultural change as well as its causes. Moreover, world prehistory balances out treatments of the past that are confined to particular national or intellectual traditions and shows us that there is real value and insight to be gained in understanding how cultures, other than our own, have developed around the planet.

Many of the contributions to this volume have a strongly anthropological perspective. Broadly defined, anthropology is the study of

humanity, and it is composed of a number of distinct subfields that examine the biological, cognitive, linguistic, and cultural variability of our species. Anthropology offers a unique window for understanding the past because of its comparative perspective and its engagement with societies at all levels of complexity, ranging from the simplest of hunting and gathering peoples to the most complex of nation-states. Furthermore, anthropologists have documented tremendous variability in human cultures, a finding that reminds us that our species has evolved in a diversity of environments and that there is no single optimal biological and social adaptation. Thus, there are numerous forms of the human family, of kinships systems, of expressions of religious belief, and of political leadership. At the same time, however, anthropologists have discovered a number of broad regularities in human cultures that allow us to use some findings as analogies that help us understand what past societies might have been like. For instance, we can observe today that hunters and gatherers who live in arid environments characterized by limited resources necessarily move their residences frequently over the course of a year. If through archaeology we discover the remains of

This era begins deep in the past, some five million to eight million years ago, and ends around 4000 BCE. Our species did not exist at the beginning of this era, but paleontologists and paleoanthropologists are confident that they can recognize ape species that are on our direct line of evolution.

hunting and gathering peoples who lived in a similar environment 10,000 years ago, we can hypothesize that these ancient peoples likewise moved their residences frequently. By themselves analogies prove nothing, but they are used constantly to test our ideas about the past and to gain insight into past lifeways.

This era begins deep in the past, some five million to eight million years ago, and ends around 4000 BCE. Our species did not exist at the beginning of this era, but

paleontologists and paleoanthropologists are confident that they can recognize ape species that are on our direct line of evolution. These species are confined to a relatively small part of Africa. Although we know little about them aside from their fossilized remains, it is likely that they resembled modern chimpanzees in their social organization. They probably lived in small groups and foraged individually for their food. Their social lives revolved around reproduction, dominance hierarchies in which larger and more aggressive individuals maintained social prominence, and a limited recognition of biological kinship, that between mother and offspring. By the end of the era, the foundations of most of the major civilizations in the Eastern Hemisphere have been established, while those in the Western Hemisphere are in their formative stages. Although there are numerous hunting and gathering peoples to be found across the globe, many more people are now living in villages, towns, and, in a few instances, large cities. New subsistence technologies, such as the domestication of a bewildering variety of plants and animals, are widespread, as are technologies that have led to the creation of metal tools, textiles, and ceramics. New social relationships have emerged as societies become more complex, and in some places people now live under the rule of hereditary rulers and in profoundly

nonegalitarian circumstances. Instead of dominance hierarchies, people now live within a complex web of social rules, mores, and expectations. And instead of being found only in Africa, our species now lives in virtually every part of the world, from the driest of deserts to the highest of the world's plateaus. Finally, the earliest writing systems are just appearing in the ancient Near East, and in a sense this begins the times of literate societies and civilizations.

This era, then, describes the profound and extraordinary biological and cultural changes of our ancestors. It is hard to express just how extraordinary these changes have been. Not only has our species undergone dramatic physical change over these millions of years—for example, in comparison with some of our primate relatives and ancestors, we walk on two legs rather than four, we use our hands effectively as tools, and we have larger, more complex brains—but the cognitive changes in our species are equally, if not more, significant. Today, we speak thousands of languages, and even more importantly, some of us can learn them with facility. But for most of our evolutionary history, our ancestors had no real spoken language and had to communicate with gesture, action, and calls. And although we recognize that our closest primate relatives such as chimpanzees and gorillas have real intelligence, it is not of the same richness, complexity, and quality of that which characterizes our own species. Humans have a capacity for symbolic communication—the use of verbal utterances, gestures, and even objects—to represent ideas, concepts, people, and actions that are not physically present. Thus, humans can live not only in the here and now but can also describe both past and present and can create ideas and scenarios that have never actually existed in the physical world. None of our close primate relatives has this ability to any significant degree.

Scholars of this deep past have not only attempted to document these changes but have also actively sought to explain them. Among other things, the contributions to this volume will provide information that can be used to address a number of important themes, questions, and controversies about the evolution of our species and the creation of the rich cultural tapestry that characterizes the distant past. At the same time, these contributions will provide a detailed look into how scientists have studied our past and how difficult it has been to create a comprehensive and detailed understanding of that past.

What is it that makes our species human? What evidence is there in the past to say that one of our ancestors was “human”? We call ourselves *Homo sapiens sapiens* (“wise” or “thinking” human), our biological nomenclature, with *Homo* representing our genus and *sapiens* our species. We have a fossil ancestor that paleoanthropologists call *Homo habilis*, the so-called “handy man” because of the location of the thumb on the hand. This species made simple stone tools associated with two different technological traditions, an early one called Olduvan found at 1.8 million to 2.2 million years ago and a somewhat later tradition called Acheulean, which is dated between 1.8 million and 1.5 million years ago. Is the ability to make stone tools sufficient to assign this fossil find to the genus *Homo*? No, because the fossils of at least two other species—*Australopithecus aethiopicus* and *Australopithecus*

garbi—are found associated with tools of the Olduvian tradition. Why *Homo habilis* is in our genus is a combination of physical characteristics including a larger brain, a reduction of tooth size especially in the cheek (or grinding) teeth, and a larger brain-to-body ratio when compared to the contemporary australopithecines. These physical changes are said to signal a more intensive use of technology, which is believed to reflect an increased level of cognitive development.

This example offers a number of insights into the problems faced by the scientists working within this era. The data upon which conclusions

Why Homo habilis is in our genus is a combination of physical characteristics including a larger brain, a reduction of tooth size especially in the cheek (or grinding) teeth, and a larger brain-to-body ratio when compared to the contemporary australopithecines.

are based are fragmentary and sparse, and consequently many inferences are tentative at best. Also, fossils and stone tools tend to provide little insight into the social lives or behavior of these remote ancestors. Although archaeologists have made every effort to obtain evidence for food sharing, for example, by looking carefully at the distribution of animal bones at the sites they excavate, it is usually the case that these sites have been badly disturbed by erosion, animal activity,

and landscape changes since their deposition many years ago, all of which make it difficult to make an objective assessment of these past behaviors. History, then, in the earliest times of this era is based on fossils; comparisons of them with both later and earlier specimens, stone tools, and animal bones; and whatever tentative inferences can be drawn from them. As already noted, analogies also play a very significant role in our understanding of deep prehistory.

The fossil record, however, can only go so far in providing evidence for the appearance of our species. The earliest fossils that paleoanthropologists have identified as being *Homo sapiens* are found in Africa as early as 200,000 years ago. However, their skeletal characteristics are described as “transitional,” meaning that they are a blend of primitive and modern features. Fully anatomically modern *Homo sapiens* are not recognized until 125,000 years ago, again from Africa. But if these finds resemble us physically, were they modern in their behaviors? What behaviors would qualify as “modern”? Long lists of traits have been proposed, including the appearance of figurative and nonfigurative art, clear evidence of deep planning in terms of subsistence practice, the use of decorative body ornamentation, the creation and habitual use of a wide diversity of tools, especially those made of organic materials, and much more. Not surprisingly, given the Eurocentrism of many early paleoanthropologists, behavioral modernity was first proposed to have appeared in western Europe around 50,000 years ago, and the cave art found at sites like Lascaux, Altamira, and others was said to support this inference. Some scientists have proposed that the spark that created this so-called cognitive revolution was the appearance of fully human language and its habitual use. But more recent data, again from Africa, suggest that many aspects of behavioral modernity appeared at least as early as 70,000 years ago and possibly even earlier. Although the

European finds reflect modernity in the sense meant here, they are no longer believed to be the earliest expression of it. There is even evidence of body ornamentation dated to 100,000 years ago. Were the makers human? In one sense, yes, they were. But it is unlikely that they had the full range of behaviors we associate with modernity. In any case, it is important to remember that the evidence from the study of world prehistory is that our evolution has been complex and has varied considerably across geographic space and that, as a consequence, there is no finish line that one of our ancestors crossed in some race to become human. Becoming human is not an event; it is a process.

Data on our biological and cultural evolution remain relatively sparse for most of our past. But by 10,000 years ago, we routinely discover buildings and structures, elaborate artistic expressions, and significant quantities of food remains and broken artifacts. And as we near the end of the era, the quantity and range of physical objects left behind by our ancestors—from skeletal remains to the by-products of their technologies—grows tremendously. Although many of these early villages and cities are small by modern standards, they are larger and more complex by orders of magnitude than the remains created by our earliest ancestors. And while changes in landscapes due to erosion, sea-level rise and fall, and the movement of glaciers, for example, have destroyed or damaged many archaeological sites, many more sites have been discovered, resulting in a richer archaeological record. This means that it is much easier to get at the social lives of our ancestors than in earlier times, which in turn means that we are better able to develop a more complete historical perspective on these cultures and the peoples who created them.

How much influence did climate and climate change have on human biological and cultural evolution? We know that in the modern era anthropogenic global warming is creating significant problems for peoples living on low-lying islands in the Pacific as well as hunters living in the Arctic. If any of the more dramatic scenarios of sea-level rise come to pass within the next century, coastal cities around the world will be inundated, and the people living in them will be forced to adapt to these radically different environments.

Similarly, we can look at past environments and ask to what extent changes in the natural world shaped the direction, pace, and flow of the evolution of our species. A number of our ancestors, including *Homo erectus* (“upright human”) and our close relative *Homo neanderthalensis* (Neanderthal human), lived during some of the coldest periods the world has seen over the past 500,000 years. Insofar as it can be observed in the archaeological record, neither of these species had the technologies to create complex clothing, that is, with tight seals that fit the body snugly and preserve its warmth. Some paleoanthropologists have argued that aspects of the Neanderthal skull, such as the large nasal cavity, were adaptations to cold stress that allowed inspired

A number of our ancestors, including Homo erectus (“upright human”) and our close relative Homo neanderthalensis (Neanderthal human), lived during some of the coldest periods the world has seen over the past 500,000 years.

air to be warmed more effectively before being drawn into the lungs. The relatively compact and heavily muscled body and short limbs relative to body size are indicators of an adaptation to cold because this morphology of features has less surface area, which reduces the amount of heat lost through the skin. For much of the early history of our species, changes in our biology and physiology were as important as changes in our behaviors.

Through time, however, cultural adaptations tend to become more important than changes to our bodies and biology. *Homo sapiens* and *Homo neanderthalensis* coexisted in what is now Europe for thousands of years, but by roughly 30,000 years ago the Neanderthals vanished from the region. Many hypotheses have been advanced for this, including violent conflict between the species and a competitive advantage for humans given their superior ability to use language as well as interbreeding, wherein the Neanderthal genome would have been absorbed into the human gene pool. None of these explanations has much evidence to support it. However, a hypothesis focusing upon a cultural adaptation—the appearance of a gendered division of labor—may offer some insights into this problem. All human societies have a division of labor based on gender. In hunting and gathering groups, men tend to hunt large dangerous game, while women, old men, and children gather plants and capture small game. Together, these different strategies offer the possibility of creating a more secure and varied (and therefore healthier) diet. Moreover, if one food strategy fails, the other may well succeed. Using archaeological data of animal bone assemblages and comparing Neanderthal sites with those of humans, it has been observed that the diversity of resources at the human-created sites is far greater than that of those created by the Neanderthals, suggesting that the humans of the era had a gendered division of labor. In contrast, for the Neanderthals, it is suggested that both males and females cooperated in the hunt. Because humans were able to obtain a healthier and more secure diet, they were better able to overcome periodic or unpredictable resource shortfalls and scarcity than were the Neanderthals because of their culturally derived ability to shift their resource procurement strategies.

Cultural adaptations such as these become the dominant force in cultural change after 15,000 years ago, and the pace of cultural change accelerates rapidly at about 10,000 BCE. The increased pace of change coincides with the global shrinking of the ice sheets that covered much of the Northern Hemisphere. Glaciers and ice sheets have been a common feature of the planet's climate throughout human evolution but only had a significant impact on it after our species moved out of Africa and into higher latitudes, where cold temperatures and aridity were more pervasive. Although the movement back and forth of ice sheets did not affect the daily lives of our ancestors, since the changes were slow and thus imperceptible at the scale of a human life, the regular back and forth of glaciers created short periods of warmth followed by longer periods of cooler and then colder temperatures. This process created a patchy, fairly unproductive environment. At 10,000 BCE, however, the glaciers retreated northward or up into high mountain valleys and have remained there since. Consequently, global climate has wit-

nessed an unprecedented period of stability characterized by warm temperatures and remarkably little variability.

Around 10,000 BCE we find that cultures in a number of places, primarily Mesopotamia, East Asia, and possibly the Nile Valley, begin a process of sedentarization. That is, although these peoples still practiced hunting and gathering lifeways, they no longer made frequent residential moves. In other words, they began to stay longer in fewer places and, in some cases, became fully sedentary, living in the same place for the entire year. The relatively mild climate of the time created an abundance of wild resources of all kinds, some of which were the ancestors of modern domesticated plants like wheat, barley, millet, and rice. According to some archaeologists, this new abundance created the conditions for sedentary life as populations became more dependent upon them and were thus tethered to them. One consequence of becoming sedentary is a more rapid rate of population growth. Although population densities were fairly low on a global scale, they became very high in these zones of abundant natural resources. For a time, there were sufficient resources in these areas to support larger numbers of people. And as densities grew larger, some groups migrated to other areas. Over time, however, wild resource density was not sufficient to support these ever-growing populations. This has led some archaeologists to argue that population-resource imbalance was the primary cause of the domestication of plants and animals in these regions.

But was climate change the ultimate cause of the domestication of plants and animals? There seems to be little question that the end of the glacial epoch facilitated domestication because of reduced climate variability. Moreover, there is no archaeological evidence of any kind from earlier in prehistory to suggest that plants or animals (aside, probably, from the dog) were domesticated. In this instance, it seems that it is best to label the onset of a stable climate a necessary condition for plant and animal domestication rather than a sufficient condition. But to put this argument into perspective, there is evidence from other regions of the world that some plants and animals were domesticated for very different reasons. Some plants, like chiles, were domesticated as condiments, while others, such as cotton, were domesticated to facilitate the harvesting of vast schools of anchovies off the coast of ancient Peru. Here is where a world prehistory becomes important, because it reminds us that there is no single “necessary” story to be told about the evolution of our species; instead, there are multiple contingent stories with very different causes and outcomes.

Whatever the causes of plant and animal domestication, however, there is no question that the creation of an abundant, reliable, and renewable subsistence system based on different combinations of domesticated plants and animals was causal to the veritable explosion of culture after 10,000 BCE. But not every part of the world was a part of this change.

Here is where a world prehistory becomes important, because it reminds us that there is no single “necessary” story to be told about the evolution of our species; instead, there are multiple contingent stories with very different causes and outcomes.

The Middle East, especially the Levant (eastern Mediterranean coast) and Mesopotamia (roughly present-day Iraq), along with some of the major river drainages in East Asia, were precocious. Eastern and central Europe saw the introduction of domesticates somewhat later, and still later was northern Europe and, surprisingly, sub-Saharan Africa. The explosion of culture in the Western Hemisphere was even later. And some places, like Australia, parts of southern Africa, and the Arctic, never developed indigenous, or local, forms of complexity, although these societies were certainly impacted by their more complex neighbors.

When does the world become truly global? When do societies move from being local to regional to supraregional? There is no question that for most of human history, we have been a profoundly local people. Although our ancestors moved out of Africa and populated the planet, we have to remember that these moves were piecemeal and took place over thousands of years. There was no organized migration out of Africa but instead a series of local moves that are best seen as part of the subsistence quest of these peoples. The peopling of the Americas is a good example of this. The earliest peoples who “discovered” it were not looking for it but were instead in search of the next good place to camp and find something to eat. None of those people who crossed the Bering Land Bridge or floated down the west coast of North America had any idea that there was a continent behind that coastline or ahead of them over the next rise.

We become more regional fairly late in our history. We can track this by looking at where artifacts come from and how they move across the landscape. There is evidence of small-scale exchange between groups of hunters and gatherers as early as 120,000 years ago, but the geographic scope of this exchange is still fairly limited. It is only near the end of the Paleolithic period that trade networks that were more regional in scope began to emerge. The trade of obsidian, a volcanic glass, involved the movement of raw materials over hundreds of miles from sources in Turkey to destinations in the Levant and elsewhere in the Middle East. This kind of regional exchange became fairly common after the end of the glacial era, as people began to live in sedentary communities and rely more extensively on domesticated plants and animals.

But we did not become more global until the very end of this era, around 4000 BCE. The exchange of precious stones, foodstuffs, textiles, and metals appears to have been important in the formation of the earliest states in the Old World. Connections over thousands of miles from the Indus to Mesopotamia are now well documented. But the very large majority of people living at the time were still quite local in that most probably never ventured far from the villages in which they were born. A global outlook was held by the traders and by the people, mostly elites, who benefited from the trade networks and who could afford to support them.

World prehistory offers us insights into our deep past and provides us with an understanding of what it means to be human. It shows us that our past is a truly complex mosaic of events, processes, and outcomes that have shaped the biological and cultural evolution of our species. And while we see tremendous variability in the expression of

culture in the past, we must not forget that there are similarities in our cultures that cross both space and time. Indeed, it can be argued that many of the foundations of the things we take for granted today, such as the way in which our minds frame problems, assess risks, and make decisions, were fixed when anatomically modern *Homo sapiens* made its first appearance some 125,000 years ago. Our mechanized agricultural systems of the modern era are ultimately based upon the decisions made by peoples living more than 10,000 years ago confronted with difficult choices about maintaining their subsistence systems in the face of population growth. We today owe much to our ancestors no matter where they are from, for ultimately they have created the foundations of what we are as humans and how we live in the world.

Environment and Population

The story of human biological and cultural evolution can be usefully summarized as a story about adaptation to the environment. Adaptation is the process by which a species creates a stable lifeway within a specific environmental context. As mammals, we live within a habitat, which can be broadly defined as the physical location within which we live. Within these habitats are multiple niches, which describe the specifics of how we actually make a living: what it is we eat, how we go about obtaining what it is we eat, and how we modify the niche to make it more productive for our ends. We do not simply respond to the environment, but instead we are actively involved with it. As cultures became more complex over time, their ability to modify the environments (or niches) within which they lived increased dramatically. Once domesticated plants and animals became the basis for the diet in many regions of the world, we were no longer dependent upon the natural abundance of plants and animals. But this did not mean that we were free from the environment, because the advent of agriculture meant that in many instances, people became more dependent than ever on predicting the timing of rainfall, the probability of frosts, or other climatic events that could dramatically reduce the yield from their fields and crops.

Even today we are very strongly affected by the environments in which we live. Many scientists believe that anthropogenic global warming—the rise in the earth’s temperature that can be attributed to human agency—began at the end of this period, about 4000 BCE, as a larger proportion of the planet’s inhabitants became farmers and herders. These subsistence technologies are known to produce significant quantities of greenhouse gases, such as methane and carbon dioxide. If some of the more dramatic predictions of sea-level rise from this warming occur within the next century, many coastal cities and low-lying islands across the globe will be inundated, leading to massive economic dislocations and migrations of people from these places into more interior regions. Although the environment itself is not a constant, what is constant is the continual necessity of our species to adapt to the constraints and opportunities of environments and their changes over time.

For much of the evolution of our species we have adapted to our niches, as have all other species, by changes in our biology or our physical characteristics and, to a lesser extent, modifications to our behaviors. Thus, many of the contributions of this theme focus on the physical characteristics of our distant ancestors and describe how they may have made a living based in great part upon the inferences we gain from studies of their skeletal morphologies. Indeed, for the first five million

years of our evolution, we responded to environmental change, as did our neighbors within the environment.

But what distinguishes our evolutionary history is the degree to which we have come to rely on technology as our primary means of adaptation to the environment. Compared to many of our closest primate relatives, we are physically quite weak, have small teeth, and are fairly slow. Without our tools, few if any of us would fare as well as an adult male chimpanzee in a confrontation with a jaguar. But it is very unlikely that the chimpanzee would be able to adjust to a significant drying of the climate. Tools, as well as the mental capacity to invent

them and use them in novel ways, make all of the difference to our successful adaptation to the changing environments of the past and have made us—our species—what it is today.

Thus, as tool use becomes more common, we can observe that once-critical physical characteristics become diminished in importance. For example, many of our earliest ancestors had large, robust molars that helped them chew the gritty

foods they ate. Reliance upon chewing was also manifest in the shapes of their skulls, which themselves had to be robust for the attachment of the powerful muscles that permitted constant intense chewing. As our ancestors began to use tools, rather than their bodies, as the primary means by which to process the environment, molar size began to shrink, and skulls became less robust. Albeit slowly, technology trumped biology as our primary adaptive mechanism.

The advent of reliance on technology also meant that our ancestors could move into or even create new niches. Most animals are very much confined to their niches by their diets, dentitions, and limited range of behaviors. Many species are unable to cope with dramatic and rapid environmental change and have thus gone extinct. Our great capacity for tool use means that only the most severe, long-lasting, and persistent changes in the environment will threaten our survival. Our minds and our ability to make tools of all kinds mean that we can move away from problems more effectively than other species. Much of the early movement of our ancestors across and then out of Africa may have been in part due to movement away from scarcity of food or water in the distant past.

Dealing with challenging environmental contexts, however, is only one part of the story of our species and its evolution. Successful adaptations create stable and even growing populations. Population sizes are held in check by predation, disease and illness, and failures of some individuals or groups to reproduce. Many of our early ancestors were a prey species for large carnivorous animals like large cats and canids, such as wolves. For most of the evolution of our species, population sizes were very small.

As technology became more important as our means of adaptation, our ancestors could defend themselves more effectively against predators and move further up the food chain. Although there is continued

Without our tools, few if any of us would fare as well as an adult male chimpanzee in a confrontation with a jaguar. But it is very unlikely that the chimpanzee would be able to adjust to a significant drying of the climate.

debate as to whether ancestors such as *Homo ergaster* or *Homo habilis* were hunters or scavengers, it seems clear that *Homo erectus* was capable of hunting large mammals, and hunting was one of the most important subsistence technologies for *Homo neanderthalensis* as well as early *Homo sapiens*.

But a successful adaptation to a niche with an impressive technology does not guarantee rapid population growth. Most of our early ancestors and indeed most people on the planet until roughly 10,000 years ago were hunters and gatherers who had a mobile lifeway, and their subsistence strategies depended in great part upon the natural abundance and seasonal availability of the plants and animals important to their diet. Depending on the number of residential moves, women in hunting and gathering societies tend to have lower completed fertility than do women in more sedentary societies. The interval between births is greater for mobile women, and this acts as a powerful mechanism to depress rapid population growth rates.

After 10,000 years ago, a number of peoples began to adopt more sedentary lifeways. This process is related to, but not caused by, the domestication of plants and animals. In the ancient Levant, for example, the Natufians became sedentary by their focus upon large stands of wild barley and wheat. Populations began to grow rapidly in the region, but over time the pace of growth could not be supported by the harvesting of wild resources. In the Levant, this ultimately led to the domestication of these species. Similar processes likely took place in East Asia and in Mesopotamia. As subsistence systems based upon domestication became more widespread, populations grew exponentially. Ultimately, it is plant and animal domestication that has been the engine of population growth on our planet.

The contributions in this theme cover three important topics: a description of the primary methods used to study the ancient past, an overview of the evolution of our species starting almost five million years ago, and finally a review of the adaptations and lifeways of our ancestors over the past two million years. To study the deep past, information from a number of scientific disciplines is required, including archaeology, paleoanthropology, paleoclimatology, geology, molecular genetics, and linguistics. For the very earliest of our ancestors, we rely almost exclusively upon paleoanthropology, climate reconstructions, and geology. The remains of our ancestors are fossilized, and aside from the stone and sometimes bone tools they used, there is little direct evidence about their lifeways. Climate reconstructions help us define the niches in which they may have lived, while geology is used to provide chronological dates of when particular fossils were deposited into the archaeological record. Based upon these limited data, we make the best inferences possible as to the range of adaptations our ancestors may have employed.

As we near the modern era, other disciplines can contribute effectively to developing a story about the past. Although studies of skeletal anatomy remain important, in a few cases it is possible to identify the DNA contained in ancient bones. Currently, scientists are working to decode the Neanderthal genome; this is the most ancient of our ancestors to which this technique has been applied. The analysis of DNA,

however, in more recent times can be used to study population movements, patterns of interaction, and, in some cases, the relatedness of individuals found in ancient cemeteries. Archaeology is of considerable importance since our more recent ancestors were now leaving behind many more kinds of objects and creating many different types of archaeological sites. Through careful excavation and analysis of the materials recovered, it is possible to determine the adaptations of these peoples. Dating methods continue to be of great value. Finally, there are some opportunities to use the methods of linguistics to track population movements. Combined with the study of ancient DNA, this has become a very powerful approach to the study of the past.

—Mark Aldenderfer

■ Introduction: How We Study the Very Distant Past

Because prehistory is not preserved in memories or revealed to us in written records, scientists must rely completely on other forms of evidence for reconstructing it. Many of these methods are the same as those used to study historical periods, but there is no written record to verify the clues or to lead to new ones. The record of prehistory is restricted to the materials that have lasted thousands or millions of years in the ground and to those that have persisted for thousands or millions of years in our behavior, in our anatomy, and in each of our cells. Crumbly pots, dusty bones, regional tongues, and swabs of molecules are surprisingly telling when it comes to ancient history.

Prevailing over all the study of human prehistory is the understanding that humans share a common ancestor with every living thing, an idea championed by Charles Darwin. Ever since our humble beginnings we have been evolving, are currently evolving, and will continue to evolve as long as every child is not a clone of its parents and as long as every new generation is different from the one before it.

When it comes to our prehistoric past, nature, not scribes or journalists, wrote the story. Our biology and much of our behavior evolved by natural selection favoring certain traits that later became adaptations, by new favorable and not-so-favorable mutations in the genetic code, by bottleneck effects that restricted population

variation, and by gene flow between populations that spread variation around.

The traits particular to our species—including upright walking, an enormous brain, and a dynamic intellect—began evolving about six million years ago when the branch leading to *Homo sapiens* split from that leading to chimpanzees. Just as if we were interested in horses or dogs, most of the evidence for our prehistory comes in fossilized teeth and bones, in comparative anatomy, in ancient DNA, and in our own DNA. The rocks and the sediments that contain the fossils and the artifacts also hold geologic clues about the ancient environment and about the age of its contents. The only thing that is different about human evolutionary studies compared to other animals is the additional material culture and linguistic evidence that help reconstruct much more recent prehistoric life and human dispersals.

Humans are the result of millions of years of modification, and our adaptations are those bouts of tinkering that succeeded and that benefited our species over generations. With all that remains of these processes in the ground and in our bodies, scientists must reconstruct the experiments that nature has performed on us. Such a task requires creativity, tenacity, and technology. Creativity is imperative for asking the right questions and for figuring out the means by which to answer them. Tenacity and

stubbornness are traits that no scientist who is searching for evidence can do without. Technology helps scientists to see the evidence they have collected in ways that their naked eyes cannot. Cutting-edge methods also allow them to collect rare and fragile evidence, like bird blood residue on a 30,000-year-old arrowhead. Of course, luck plays a role as well, but the most successful scientists put themselves in luck's crosshairs more often than the rest.

It did not take modern science and technology for Darwin to figure out most of how the natural world, including humans, evolved. Thanks to a trip around the world on the HMS *Beagle*, he got a global perspective on geology and biological

variation. From his own backyard and through correspondence with peers all over the world, Darwin collected evidence from living animals, from dead ones, and from extinct ones to argue that everything is related and belongs somewhere on the metaphorical Tree of Life. By grouping extant animals into nested categories, it is possible to make predictions about where they shared a common ancestor in evolutionary history. Thus, since chimpanzees and humans share more features and behaviors than either does with fish, one would predict, accurately, that the extinct ancestors to chimpanzees and humans would be found in more recent layers of the earth, which were laid down later in the evolutionary history

of life on earth, compared to the common ancestor we share with fish. This comparative method extends all the way down to the molecules. DNA from humans and chimpanzees is more similar than either is to that of any fish, and when the differences between humans and chimpanzee genetic sequences are counted up, it is possible to estimate how long those differences took to accumulate (molecular clock analysis). Most studies like this estimate that humans and chimpanzees shared a common ancestor between six million and five million years ago and have been evolving independently ever since.

If a scientist is searching for the very first human ancestor, then they would first go to a geologic map and find sedimentary rocks that are between six million and five million years old. Chances are that this event took place in Africa, since chimpanzees and gorillas (our second-nearest relative) both live there. Thanks to the tectonic activity in the Great Rift Valley of East Africa, rocks of this age have been exposed for paleontologists to crawl all over, collecting fossils that have eroded out of the sediment. Millions of years of volcanic activity in this region have laid down periodic layers of ash, which are spread between fossil deposits and are datable using modern geochemical methods. This is probably how the paleontologists knew to survey these rocks in the first place, and if not, then once it is dated this is how future researchers will know where to search for the first fossil human ancestors. Much of the last six million years is represented by fossils and stone tools and other artifacts from East Africa thanks to the unique geology of the region. Because so much of what we know about human evolution and prehistory comes from work done in East Africa, it was nicknamed the “cradle of humankind.”

Evolution, Natural Selection, and Adaptation

The late biologist Theodosius Dobzhansky wrote an essay in 1973 that summed up the state of biological science at the time in its title, “Nothing in Biology Makes Sense Except in the Light of Evolution.” Even as the theory of evolution comes under renewed attack at the beginning of the twenty-first century by those who feel that it threatens their religious beliefs, it is virtually impossible to find a biologist—or scientist in many other disciplines—who will find fault in Dobzhansky’s claim.

Evolution is the theory that explains how species appear and change over time. These changes consist of characteristics readily seen (known as the phenotype), such as plumage patterns in songbirds, but also in characteristics not so easily observed, such as the genetic composition (or the genotype) of organisms. Evolutionary adaptations affect virtually all aspects of an organism’s life, from success at obtaining mates to disease resistance; thus, evolutionary theory provides the foundation upon which our understanding of modern biology is built.

While ideas that could be labeled “evolution” were being proposed in the eighteenth century, the first expression of the theory of evolution as we know it was in a brief unpublished sketch by Charles Darwin in 1839 shortly after his return from the HMS *Beagle* expedition, which inspired his thinking on the topic. Darwin showed a revised copy of it to Joseph Hooker in 1844. Darwin knew that the ideas were controversial and spent much of the next two decades testing and revising his initial ideas and acquiring evidence that would help him make the case. He was forced into action in 1858 when Alfred Russel Wallace, a young biologist and explorer, sent Darwin an essay expressing very similar ideas. Darwin forwarded the paper to Sir Charles Lyell, who, with Hooker, had excerpts of both Dar-

win's and Wallace's work read at the July 1, 1858, meeting of the Linnean Society in London.

The theory of evolution posits that those individuals better able to acquire resources and avoid predation and who are more resistant to disease or possess similar positive traits within a given environmental context will be more likely to have viable offspring who, because of heredity, will likely inherit the characteristics that gave their parents an advantage over other members of the species. Over time, those with these positive traits will outbreed those without, and the population will change to reflect the increasing frequency of those better able to take care of themselves and their offspring. This is known as differential reproduction. The result of differential reproduction—the weeding out of individuals with less-adaptive traits and the gradual accumulation of favorable traits within the population—is what Darwin called natural selection. Through natural selection and assuming no environmental change, those organisms that produce more offspring within a specific ecological niche are said to be better adapted than those less able to do so. However, if the environment changes, different traits may become advantageous, and those traits that once may have enhanced adaptation no longer do so. In this sense, natural selection is “blind”; that is, it assumes no directionality and is contingent on the stability of the environment occupied by the organism.

Darwin and Wallace lacked a mechanism for inheritance, however, and Darwin died never knowing that the basic laws of inheritance had been discovered by Gregor Mendel, an Austrian monk who demonstrated through his studies of pea breeding that the inheritance of some traits was particulate and that patterns of inheritance of some traits could be explained by simple mathematical formulas and ratios. While Mendel's work remained unknown for several decades, it was rediscovered at the turn of the twentieth century, and in 1905 the particulate entity of inheritance was renamed the gene by William Bateson.

Although DNA (deoxyribonucleic acid) had been identified in 1869, its role in inheritance was not recognized until the early twentieth century. It is now known as the substance that carries genetic information in the cell nucleus

and is organized on chromosomes. The modern evolutionary synthesis combines the key concept of natural selection with our enhanced understanding of genes and their organization at the molecular level, including how they change through mutation, thus supplying the raw material for natural selection. In the modern synthesis, evolution can be understood as changes in gene frequency in populations of organisms over time. Adaptation, then, can be seen as genomes (combinations of genes on chromosomes) that confer reproductive benefits on organisms within specific environments.

Darwin himself saw significant evidence that something like evolution had occurred; in fact, that evidence is what made him change from a believer in the special creation of each species to the leading proponent that species evolved over time. Among the strongest evidence for evolution at the time was the fossil record that revealed many species that existed at different times in the earth's past. Some fossils appeared related to modern organisms, while others did not. Changes in fossils as revealed by examination of a sequence of geological strata reveal evolutionary developments in the line of organisms examined. The fossil record is sparse, however, as few environments on earth produce conditions that favor fossilization (i.e., burial of the remains of an organism in a low-oxygen or anoxic environment that prevents or limits decomposition).

Anatomical comparisons among living organisms as well as among living and extinct species can likewise reveal much about how a group of organisms has changed over time. For instance, humans and apes share a common ancestor. Humans and apes are typically born with the same number of teeth, but because the length of the human jaw appears to have shortened since humans and apes diverged from one another, adolescent and young adult humans have to endure the agony of having their wisdom teeth removed; for many of us, our jaws are too short to accommodate all the teeth.

The biotechnology revolution has also added to the arsenal of evidence in favor of evolution. By examining mutation patterns in genes among a group of nominally related individuals, molecular analyses may provide a powerful, objective confirmation of evolutionary pathways worked

out via fossil and anatomical analyses. For example, humans and chimpanzees share approximately 98 percent of their genetic material and genes, but that 2 percent that is distinct makes all the difference.

Not only can molecular evidence be used to reconstruct relationships among groups—with closely related groups being more similar genetically and vice versa—but by focusing on segments of the genetic code with more or less constant mutation rates, the timing of events in the history of a group of organisms can be estimated. While these analyses can be used as checks against estimates of the timing of events as recorded in the fossil records, they make it possible to obtain estimated dates of evolutionary events in organisms that leave few traces in the fossil record.

Archaeology

Archaeology is the study of human culture through the analysis of objects created or modified by humans throughout their past. The list of objects used in archaeological studies is almost limitless. Buildings, boats, burial sites, cave paintings, clothing, jewelry, roads, and tools are just some of the types of materials that have been examined by archaeologists.

Traditionally, archaeology has been subdivided from history based on one factor: whether or not the culture of interest had some form of written language during the time period of interest. If no written language was evident, the study was deemed to be archaeological; otherwise, it was deemed to be historical. Despite tra-

dition, the boundary between the disciplines is often blurry. For example, a study of Druidic culture in the British Isles may use historical analysis of Roman writings but also archaeological analysis of a Druidic site.

Most information about the past is obtained through excavation of ancient sites. In the past, archaeological excavations (or digs) seemed little more than academic ransacking of ancient sites. Heinrich Schliemann, in his search for Homer's city of Troy, destroyed a number of upper layers in the mound at Hissarlik, Turkey, in his search to reach a layer destroyed by fire (Troy II) as described by Homer. Many other archaeologists of his time were equally destructive.

Before a modern dig begins, a potential site is usually surveyed to locate areas within the site worthy of further investigation. Survey methods include walking or flying over a site to spot features that do not quite fit in with the natural landscape. Aerial photography and remote sensing data—especially side-looking airborne radar, sonar, and magnetic surveys—can help pinpoint structures of interest buried beneath the surface of the landscape.

Surveys may be supplemented by subsurface sampling techniques. Such samples may be obtained by coring and analyzing the cores for artifacts of interest. Test pits—in essence mini-excavations—are also used. Surveys and sampling minimize the risk of damaging the natural and cultural landscape as well as minimize the risk of wasting resources on an unproductive location.

Modern archaeology follows four basic principles (or laws) espoused by Edward C. Harris in the 1970s. The first of the laws is that of superposition: in undisturbed terrain, upper strata (layers) are younger than layers beneath. The second is the law of the original horizontal. According to this principle, unconsolidated sediments are deposited in horizontal layers. The third law is that of original continuity. Layers will be bounded by the edges of the physical context in which they are deposited, or else they will get progressively thinner toward the unbounded edge. Finally, the law of stratigraphic succession posits that a layer of interest takes its place in a sequence between the lowest of the layers above it and the highest of the layers below.

A proper excavation is painstaking. Each layer of dirt is slowly removed, and objects discovered are carefully mapped and sketched in place. By doing so, the stratigraphy (or horizontal sequence of soil layers) of the site as well as the context of the objects therein can be preserved. Context, or the relative locations, of objects within a site is vital in determining the relative sequence of strata as well as modifications to the site through the period of interest. Relative positions of artifacts, such as grave goods in a burial site, can indicate relative importance of those objects to the persons who left them. Thus, context provides significant clues to the origin, development, and change of cultures through time.

Painstaking detail during an excavation also ensures that the provenance (provenience) of the objects is properly recorded, vital in helping determine later whether an alleged artifact is authentic or a fake.

Once removed from the ground, archaeological artifacts must be cleaned, catalogued, and classified. Some must undergo some type of conservation measure to halt or reverse degradation that has accumulated over time.

For example, the turret of USS *Monitor*—one of the ironclads that took part in the pivotal battle of Hampton Roads in the American Civil War that heralded the end of wooden warships—was, at the time this article was written, undergoing such conservation measures after it was retrieved from the waters off the Outer Banks, where the ship sank in a storm in late 1862. The salt of the oceans had corroded and compromised the iron, the turret, and other components of the revolutionary ship.

In some cases, the absolute time (such as a calendar date) that an object was created or deposited is known. Many times, though, the objects have to be dated in other ways, either indirectly from comparisons with objects of known age from other sites or directly via methods such as tree-ring analysis, radiocarbon dating, or some other radiometric technique.

Artifacts may be subject to other types of analysis. Metallurgical analyses may be used to determine materials and methods of construction of weapons. Isotopic analysis may be performed on bones and teeth from a burial site in

How the archaeological record is formed. One of our distant ancestors dies and is not buried. The bones of the skeleton as the body decomposes will be scattered by animals and the elements. Over time, the bones may be buried by the accumulation of new soil. Over time, erosion may once again expose the bones on the surface or will reveal them in the stratigraphy of a deposit. (Illustration by Jeff Dixon)

order to obtain clues about the diets of the people who lived at the site in the past.

Archaeology became more concerned with ethical practices in the twentieth century. Concerns over past archaeological looting of sites (or smuggling of artifacts from sites, as Schliemann was accused of) has led to efforts by archaeologists to work more closely with governments in the regions where sites of interest are located or with peoples with ancestral ties to sites. For example, the U.S. Native American Graves Protection and Repatriation Act (1990) is an attempt to balance the competing but equally valid needs of scientists seeking to better understand the past of the Americas with the needs of Native Americans to have their sacred traditions and sites respected.

Geology

Geology is an earth science devoted to the study of the solid portion of the earth as well as the materials that it is made of. As a science, geology has ancient roots. Humans have been studying geology to some extent at least as far back as the first time they began making tools of stone.

The first recognizably scientific studies of geology date back to Greeks such as Aristotle, but geology did not significantly develop as a science until the seventeenth and eighteenth centuries. Nicolaus Steno (Niels Stenson) laid the foundation of stratigraphy—a subdiscipline required for proper interpretation of geological layers, or strata—in his *Dissertationis Prodomus*, which was published in 1669.

Steno began with the assumption that geological deposits originate in some sort of fluid form (whether as liquid or suspended in air) that solidifies later. (Solid objects may be incorporated into soft sediments during the deposition stage.) Each new deposit is laid down on older deposits, leading to the principle of superposition: in undisturbed layers, the youngest layers are on top and the oldest are on the bottom of a sequence.

Steno observed that new strata are deposited in horizontal layers; this led to the principle of original horizontality. Thus, if strata lie at angles to horizontal layers, they must have been disturbed after they were initially deposited. Steno surmised that deposits would completely fill a basin of deposition—form one side to the other—unless some other solid object blocked the way; this is the principle of lateral continuity. A principle of Steno's is that of cross-cutting discontinuity, in that if a feature cuts through strata, that feature originated after the strata were deposited.

The principles outlined by Steno were not accepted right away—nearly a century passed before the ideas became common currency in geology—but in time they opened up huge spans of the earth's past to scientific analysis. One of the major inheritors of Steno's legacy was William Smith, a surveyor who created the first large-scale geologic maps.

Smith, while working for a coal company, noticed that sequences of specific strata were often repeated at different sites across the English and Welsh countryside. Each stratum was characterized by specific sets of fossils, and the sequences of fossils, as the sequences of strata, were repeated from one place to another. He developed a hypothesis, later accepted as a principle, of faunal succession (change) that he repeatedly and successfully tested in years of subsequent geological mapping of the British Isles. His 1815 geological map of England, Wales, and parts of Scotland is known as “The Map That Changed the World,” as much for its revelations of the geological history of the British Isles as for its innovations in the mapmaking process.

While Smith mapped the countryside, James Hutton proposed a principle that opened many aspects of the past to scientific examination: uniformitarianism. The principle of uniformitarianism, often restated as “the present is the key to the past,” contends that physical processes proceed today in the same fashion as they have in the past. Thus, a scientist can understand how some phenomenon, such as coastal erosion, operated millions of years ago by studying how it operates in the present.

Hutton also recognized the importance of the role that the internal heat of the earth played in driving geological processes. Plutonism, as the idea came to be known, claims that the heat of the interior and its effects on related phenomena, such as volcanism, are vital in the creation of basic crustal features, such as mountain ranges, that are subsequently worn down by other processes, such as weathering and erosion. Plutonism itself provided a foundation for yet another pivotal theory of geology, plate tectonics.

The origins of the theory of plate tectonics goes back at least as far as the sixteenth century, when mapmaker Abraham Ortelius suggested that the continents on either side of the Atlantic

TECTONIC PLATES, WORLDWIDE

Ocean had once been joined and had drifted apart. The first modern expression of what later became plate tectonics was made by Alfred Wegener in his proposal of a theory that others called continental drift. Wegener's ideas originated in an observation similar to that of Ortelius: that the Americas had to have once been joined with Europe and Africa. Wegener pulled together evidence from many disciplines—geology, paleontology, and biogeography, for example—in marshalling his argument that the locations of continents and ocean basins are not permanent entities (as many scientists believed at the time) but instead are temporary features of the surface that change as the continents slowly move across the earth's surface.

Wegener's proposal met with significant skepticism, but accumulating evidence from ocean basins in the latter part of the twentieth century led to the development of plate tectonics. Plate tectonics—a theory that describes the surface of the earth as made of crustal, or tectonic, plates that drift on top of a molten layer called the mantle—revolutionized geology as well as the understanding of the earth's past in that it explains the origin of major landforms, all

volcanic activity, and most earthquake activity on the planet. It is also essential in its explanation of apparently anomalous climate patterns from the earth's past, such as tropical conditions in what is now Antarctica (because it was in the past located in the tropics) as well as the current distributions of major groups of plants and animals.

Paleoanthropology and Anatomy

Paleoanthropology is the study of the evolution of humans and related primates via analysis of bones, tools, and other physical evidence. In comparison with traditional archaeology, the time spans of concern to paleoanthropologists are far greater: millions of years as opposed to thousands for archaeologists. The evidence available is often skimpier as well.

Important clues as to the evolutionary history of humans can be found through analysis of the anatomy—or structure—of bones, often the oldest and most consistent evidence of the development of humans from ancestral primates over the past several million years. Analysis of bones reveals many of the key elements of human evolution. Development of hip girdle and lower limbs illustrate the change from walking on all four limbs to bipedal locomotion. Modifications of the forelimb, especially development of the opposable thumb, make tool creation and use possible. Changes in size and shape of the skull and, more importantly, the brain case reflect physical modifications that contribute to less tangible advances, the development of the ability to reason.

Since the evidence used in paleoanthropology consists of fossils, tools, and other materials, it is strongly grounded in the principles of geological and anthropological stratigraphy, as proper dating of evidence-bearing strata is essential to placing such materials in the proper chronological sequence.

Stratigraphic techniques only provide evidence as to relative ages of strata. Other dating techniques are required, however, if actual ages are to be assigned to fossils or artifacts. The primary dating technique of use to paleoanthropologists is radiometric dating, measuring the amount of decay of radioactive isotopes in a substance to determine how old it is. Study of radioactive isotopes in bones and other objects can also yield evidence as to the nature of past climates. Isotope ratios in bones and teeth further provide clues to dietary preferences of the individuals.

The ancestors of humans and apes were primates that walked on all four limbs. A key step in the evolution of humans was the acquisition of the ability to walk on the hind legs only (bipedal locomotion). Evidence for bipedal locomotion

includes changes to the pelvis, legs, feet, spine, and skull. The ilium (the bone that forms the upper part of the hip) of humans and their ancestors is relatively shorter and broader than in other primates, allowing attached muscles to provide greater stability when walking upright. The pelvis is bowl-shaped, providing greater support for internal organs when upright.

In humans and their ancestors, the upper legs insert into the hip joint in a fashion that allows the legs to better support weight and allow for a smoother stride while walking; other apes tend to sway from side to side while doing the same. Also, the human foot, with its shorter and less flexible toes, provides a more stable platform for walking.

Another sign of bipedal motion is the curvature of the spine, which allows the spine to serve as a shock absorber as well as increases strength, stability, and balance. Finally, the position of the foramen magnum—the opening in the skull through which the brain connects with the spinal cord below—is located farther forward in humans than apes, allowing the skull to pivot in a balanced fashion on top of the spinal column when the individual is upright.

Paleoanthropological evidence also provides clues as to how long early humans have been walking on their hind legs. In particular, footprints left by two individuals of *Australopithecus afarensis* are preserved in a 3.6 million-year-old volcanic ash deposit from the Leotoli region of modern Tanzania. While *A. afarensis* was very similar to apes in terms of skull characteristics, the impressions of the feet reveal a walking motion virtually indistinguishable from modern humans.

Most primates have long curved fingers and short thumbs suitable for climbing and swinging from branches. The ancestors of humans, while retaining characteristics suitable for climbing, began evolving shorter fingers with less curvature and longer thumbs that were opposable. These advances made it possible for them to begin to manipulate objects and use them as tools.

While the ability to walk and manipulate objects were important steps in human evolution, the ability to reason is what arguably separates humans from other species. Early humans had apelike skulls: forehead sloping backward, face

projecting forward, and a fairly small brain case. As humans evolved, so did the size of their brains. To accommodate the larger brain, the skull expanded downward as well as forward, the latter leading to a relatively flat forehead. The jaw shortened as well. This coupled with the forward expansion of the skull resulted in a relatively flat face.

In addition to revealing evolutionary trends in humans and their ancestors, paleoanthropology provides important clues as to the geographical center of human evolution. While primates can be found throughout much of the world, the greatest center of diversity of hominids (a group that includes humans, the great apes, and their ancestors) is in Africa.

The early human line split from the ape line between four million and five million years ago. While there is considerable debate over which species deserves credit as the first “human,” the strongest contender for the title is *Ardipithecus kadabba*, the earliest member of the australopithecine (literally meaning “southern ape”) line known from fossils dating to 5.8 million years ago from what is now Ethiopia. *Ardipithecus* was succeeded by *Australopithecus*, most species of which are also known from East Africa.

Many scientists believe that the genus *Homo*, to which modern humans belong, evolved from *Australopithecus afarensis*, a species known from East Africa between 3.9 million and 2.9 million years ago. The first member of the genus *Homo*, *H. habilis*, is believed to have lived between 2.5 million and 1.8 million years ago. *H. habilis* was one of the first of the early humans to master use of stone tools. The leading rival claimant to that achievement is *Australopithecus garhi*, a hominid known from sites in modern Ethiopia that may have used stone tools as many as 200,000 years before *H. habilis* is believed to have done so.

Dating Methods

One of the most important tasks of anyone studying environments or societies of the past is to assign dates to sites or phenomena of interest. Without such a capability, it would be impossible for scientists of the past to determine the proper sequence of events in development of natural or human history. It would be impossible to determine what came first: dinosaurs versus primates, chariots versus automobiles, or hieroglyphics versus hexadecimal code, for example.

Sorting out the chronology of events in the life of this planet became easier with the development of material culture—especially written language—as human records often provide some date that can in time be correlated with a modern calendar. Prior to the development of written language, however, the effort to assign a date to an event or artifact becomes more difficult. Scientists have to work with clues left in a mute earth, understand the processes that created the clues, analyze the evidence, and then infer as best as possible the age of the event or artifact.

Fortunately, the earth and its residents leave quite a few signs that make dating possible. The signs are left in the proportions of certain radioactive isotopes in rocks and other materials, in annual layers of marine and freshwater sediments, in annual deposits of glacial ice, in annual bands of growth of organisms such as trees and corals, and in changes in the types and designs of human artifacts over time.

A basic way to differentiate dating methods is its type: relative versus absolute. Relative dating methods indicate whether a feature or artifact is older or younger than a comparable feature or artifact, but they are not useful in assigning a chronological age (i.e., calendar date) to the feature or artifact in question. Absolute dating methods do provide chronological ages, either exact ages as in the case of tree-ring dating or a range

of years of origin as in the case of radiometric (radioactive isotope) dating techniques.

Relative dating methods include stratigraphy in geology and seriation in archaeology. Stratigraphy is based on the analysis of the sequence of geologic deposits. By analyzing characteristic features of strata, such as a unique suite of sea-shells, presence of ash or pumice deposits, or flood deposits, and by correlating those strata with similar strata outside one's study area, geologists can work out which layers are older and which are younger, even if some geological upheaval disturbs the sequence of layers.

Seriation focuses on the development of human artifacts, such as blades, axes, pottery, or textiles. In general, a particular technology gets more sophisticated and diverse over time as its makers become more skilled and as there is more opportunity for innovation. It becomes more widespread over time if it proves to be popular; then it disappears from the record as it is replaced by a newer technology.

Absolute dating methods include radiometric dating and dating based on banded records, such as tree-ring dating and varve chronology dating. Radiometric dating techniques determine the age of an object based on the rates of decay of radioactive isotopes that are unstable (that decay, by giving off subatomic particles, and change into other isotopes or elements over time). For radiometric dating to work, a scientist must know the ratio of the two isotopes or elements of interest at the time the object was formed, the rate of decay of the unstable isotope into the other isotope or element, and the current ratio of the two isotopes or elements.

For many radioactive series, the rate of decay—typically described as half-life, or the rate at which 50 percent of the first isotope or element is converted into the other—is known and is a constant. Knowing the initial ratio of the two isotopes or elements at the time an object was formed is more difficult, but radiometric dating is limited to series in which there is a firm foundation, based on physical principles, for knowing what the initial ratio should be. Measuring the final ratio of the two elements can be done using a number of instruments, the appropriate choice of instrument determined by the isotopes or elements of interest.

No radiometric technique can assign an “exact” age—in terms of calendar date—to an object. Typically, an estimated age, plus or minus a certain number of years, is given. The range of likely ages increases with the age of the object.

One of the first, and probably the most familiar, of all radiometric dating techniques is radiocarbon dating of material of biological origin. Because of its relatively short half-life, radiocarbon dating is best done on materials less than 60,000 years of age. For older material and material not of biological origin, radiometric techniques involving other isotopes are required, such as isotopes of potassium, argon, or uranium. Potassium-argon dating and uranium-lead dating are useful for measuring the ages of things that may be hundreds of millions of years old to a few million years old. Argon-argon dating can be used to date objects hundreds of thousands of years old. For material formed within the last few centuries, other isotope series—such as those involving cesium, lead, or silicon—may be used.

A number of dating techniques rely on banding patterns produced by the annual growth of organisms or the annual accumulation of sediments or snow (ice). These annually banded records, when used effectively, can be used to assign a calendar date to the age of an object.

One of the most widely known techniques that relies on banding patterns is that of tree-ring dating, or dendrochronology. Dendrochronology analyzes annual growth increments of trees—the tree rings—in order to determine the date of some event, such as the felling of a tree used to build an old house.

Dendrochronology is often—mistakenly—referred to as tree-ring counting, but mere counting is not enough to ensure accurate dating for either tree rings or other banding patterns. First, not all trees put down annual rings. This is especially a problem in tropical areas, where strong climatically determined seasons do not exist. Even in temperate latitudes with a strong climatic influence on tree growth, some trees put on more than one band per year (a false ring), or a ring may be missing from the part of the tree sampled (a false or locally absent ring).

For tree-ring dating to be reliable, the patterns of wide and narrow rings must be com-

pared from a number of samples to ensure that no such errors occur. In addition to the overall pattern of wide and narrow rings, special features of rings caused by unique environmental conditions may also be used to check dating. All dating methods that rely on banding patterns require some type of cross-dating to ensure accuracy.

Varve chronology relies on the annual deposition of lake sediments. The layers typically alternate between coarse-grained bands and fine-grained bands, and they often differ in composition, structure, or texture. Varve chronologies have been one of the most important ways of reconstructing past environments, particularly by analyzing the pollen deposited in each year's sediments. Ice-core chronologies are developed from glaciers in which snow is deposited in a new layer each winter. The snow is modified over time to form glacial ice, which may trap samples of the atmosphere at the time the snow fell as bubbles in the ice. Such ice records have been vital in reconstructing past climates.

Similar dating techniques rely on speleothems—or annual layers of deposition of the mineral calcite in cave sediments—and growth bands in corals, the shells of mollusks, or the scales of fish.

The Reconstruction of Ancient Environments and Paleoclimates

To learn about the earth's past, a scientist must decrypt the coded messages left in the remains

of that past preserved in the earth's present. Such description is the goal of climatic and environmental reconstruction.

The raw materials that scientists may use are diverse: growth patterns as revealed in tree rings, the isotopic composition of gases trapped in ancient ice, the sequence of plant species as revealed in pollen grains trapped in lake sediments, the sequence of fossils in eons' worth of geological strata, and the chemical composition of rocks once exposed to ancient atmospheres and subsequently buried.

To reconstruct the earth's past through geological evidence, scientists must employ the techniques of geological subdisciplines such as stratigraphy and paleontology as well as of other disciplines, such as physics and chemistry. Any reconstruction of the earth's past must assume uniformitarianism, the concept that geological processes observed in modern times also operated in a similar manner in the deep past.

The type of geological evidence available depends in large part on the age of the rock formations being studied. For the time before life evolved, the chemical composition of ancient rocks once exposed on the surface may indicate the composition of equally ancient atmospheres. For example, sedimentary rocks devoid of signs of oxidation could not have been exposed to an oxygen-rich atmosphere like that of today. Similar rocks rife with oxidized minerals, on the other hand, had to have been exposed to atmospheric oxygen.

Clues such as these are strong hints that the earth's atmosphere was initially a reducing one—rich in compounds such as ammonia and methane, for example—but that it in time became an oxidizing atmosphere capable of supporting complex plant and animal life.

Certain types of rocks—especially sedimentary rocks, those formed by deposition and cementation of sediments—are associated with different types of environments. For example, the retreat of glacial ice leaves vast amounts of poorly sorted sediments—sediments composed of materials of a wide range of grain sizes—in deposits called moraines. Such deposits, in conjunction with exposures of scratched or polished bedrock, are clear signs of cold climates and associated glaciation.

In contrast, deposits of gypsum and rock salt most likely formed in shallow seas, where evaporation rates were high enough to cause the minerals to precipitate out of solution. This is evidence of hot arid climates and shallow waters such as are found in subtropical coastal environments. Likewise, carbonate rocks—even the limestone at the summit of Mount Everest—indicate a marine origin.

Fossils, in addition to indicating the evolutionary history of life on earth, also indicate the types of environments prevalent at the time the sedimentary rocks they are found in were formed. Fossils of tropical plants found in Antarctica indicate that the continent was once located in a tropical environment. Fossils of woody plants, such as those preserved in coal, can indicate the type of climate in which the plants once lived. Fossils from trees that grew in a tropical environment generally lack well-defined annual growth rings; those from trees that grew in more temperate climates possess well-defined annual growth rings.

Fossils may reveal more than the type of climate. They may also offer evidence as to the composition of the atmosphere. Photosynthetic plants, for example, require carbon dioxide from the atmosphere as the raw material from which to make, via photosynthesis, the carbon compounds necessary for fuel, growth, and development. In most photosynthetic plants, the carbon dioxide enters the leaf—the typical site of photosynthesis—via openings called stomates. While there is conflicting evidence from living plants, it appears from studies of fossil plants that as atmospheric carbon dioxide levels increase, both stomatal density and index (the latter a ratio between the number of stomates and the total number of stomatal and epidermal cells) decrease as gas-exchange efficiency between the inside and the outside of the leaf increases.

Plants provide useful evidence with which to reconstruct past climates in other ways. For example, in the Americas, the plant matter found in woodrat middens (essentially trash piles) indicates the type of plants growing in the woodrats' neighborhoods, thus providing powerful evidence as to the nature of the environment the rodents lived in. Pollen grains in lake sediments can likewise indicate the type of plant commu-

nity and, by extension, the environmental conditions that prevailed at the time the sediments were deposited.

The variation in the pattern of wide and narrow annual growth rings of trees, if properly calibrated, can be used as a proxy data set from which past climate fluctuations can be reconstructed. Variations in density of wood in the annual rings can likewise be used to reconstruct past climates. Other characteristics of the wood in the annual rings, such as scorching or scarring, can be used to reconstruct other types of events, such as wildfire chronologies or avalanche histories.

Radioactive isotopes can be used for more than merely assigning an age to an object. The ratio of some isotopes, such as oxygen-18 and oxygen-16, in the atmosphere varies with temperature. In warmer climates, the proportion of oxygen-18 is higher than in colder climates. Whether obtained from a tree-ring series or from analysis of gas bubbles trapped in glacial ice, such isotopic analysis can be used to reconstruct temperature over spans of tens of thousands of years. Isotope ratios in bones and teeth of humans and animals can yield evidence as to the nature of their diet.

Molecular Biology and Ancient DNA

Deoxyribonucleic acid (DNA) is the molecule that contains the code for life on earth. DNA is complex enough to contain thousands of genes

in an individual organism, giving the molecule the ability to direct the individual's development from birth to death, to direct innumerable chemical reactions inside each cell every day, and to record billions of years of the history of life. The latter property of DNA makes it an excellent material to examine for clues to humanity's past.

DNA owes its utility to its simple yet elegant structure. The molecule is often described as a double helix, essentially a coiled ladder in which the information is stored in the parts of the molecule that make up the rungs of the ladder. The supports of the ladder consist of alternating sugar (deoxyribose) and phosphate molecules, that is, the sugar-phosphate backbone. Unlike a typical ladder, each support, or strand, runs in opposite directions.

The rungs are made of nitrogenous bases—adenine, cytosine, guanine, and thymine—of which one is attached to a deoxyribose in the sugar-phosphate backbone. A base from one strand joins with a base from the other to form the rungs. The base pairing between strands is not random. An adenine joins only to a thymine. A cytosine joins only to a guanine. This property, called complementary base pairing, makes it possible for each strand to serve as a template to make an exact copy of the other. The genetic information is stored in the sequence of bases along the length of the DNA strand.

In a cell, each DNA molecule (chromosome) can make exact copies of itself. This enables a cell to duplicate its entire genome—or collection of chromosomes—as it divides. Each chromosome in each cell today is a descendant of the original chromosomes and cells that evolved more than three billion years ago.

Despite the ancestral connections among all of life on earth, genomes differ from species to species. Within a species, genomes differ from individual to individual. This variety is a result of evolution. Mutation, natural selection, genetic drift, and other mechanisms created genetic and ultimately individual variation.

In sexually reproducing species, recombination is a major source of genetic variation. As an individual produces sex cells—egg or sperm cells, which have half the number of chromosomes as a nonsex cell—genetic material from that individual's mother and father are mixed on

Scientist with the Penn State University Mammoth Genome Project works with the DNA of a woolly mammoth. This project is one of the first attempts to decipher the genome of an extinct animal. (S.C. Schuster & Colleagues/Penn State University Mammoth Genome Project)

each chromosome, creating new combinations of gene variants that had not existed before.

Analysis of this chromosomal variation as well as variation in the proteins coded for by genes can reveal much about relationships among individuals as well as species. Individuals that are more closely related will be more genetically similar. Species that are more closely related are likewise more genetically similar.

Because of recombination, most chromosomes in sexually reproducing organisms are difficult to use to analyze patterns of genetic variation within species. For most individuals, the best place to find suitable DNA is outside the nucleus, where most chromosomes are housed. The better alternative is in an organelle—present in all but bacterial cells—called the mitochondria. These organelles, the powerhouses of the cell, have their own chromosome. They are usually inherited only from the mother, as the father's contribution to a new individual is typically the paternal chromosomes.

Mitochondrial DNA (mtDNA) is conservative in that mitochondrial chromosomes have nothing to recombine with except themselves. It also has a higher mutation rate than most nuclear chromosomes. This suite of properties coupled with the ubiquitous occurrence of mitochondria

makes mtDNA an excellent choice for genetic analyses of maternal lineages.

In organisms whose sex is determined by chromosomes, the sex chromosomes may likewise prove useful. Mammals, including humans, have two sex chromosomes, X and Y. Females have two X chromosomes. Males have an X and a Y chromosome. Because of the possibility of recombination among X chromosomes, their utility is as limited as that of the nonsex chromosomes. But the Y chromosomes, inherited only from the father, are quite promising, as most males only have one Y chromosome, and thus there is little opportunity for recombination. While Y-DNA is present only in males, it provides an excellent (and only) option for study of paternal lineages.

Many analyses of mtDNA focus on two hypervariable regions, HVR1 and HVR2, in which an individual's sequence is compared to a reference sequence. The analysis will reveal a number of mutations, such as substitution of nitrogenous base pairs, deletion of base pairs, or insertion of base pairs. Based on the mutations detected, an individual can be assigned to a mitochondrial haplogroup that indicates the evolutionary lineage—often referred to as deep ancestry—of the individual in his or her maternal line.

For Y-DNA, analyses focus on the number of short tandem repeats (STRs) at particular locations (loci) on the Y chromosome. STRs are repeated sequences; the number of repeats offers clues to a male's paternal line. Single nucleotide polymorphism (SNPs)—single base-pair substitutions at particular loci—may also be analyzed. As with mitochondria, a male can be assigned to Y-DNA haplogroups that indicate the deep ancestry of his paternal line.

DNA sequences on other chromosomes may prove useful for other analyses. For example, several research groups are working to compare the genomes of Neanderthal man and modern humans to determine whether the two are separate species or separate subspecies. Results so far indicate that the two are closely related, but efforts to determine whether or not the two interbred—and thus whether Neanderthals left a genetic legacy to humans today—are inconclusive.

The Contributions of Linguistics

The study of modern language patterns can provide important clues to the diffusion of humans and their culture. Language is a collection of sounds and symbols that have a common meaning among members of a cultural group. It includes spoken language but also written language as well as other forms of symbolic communications: sign language, Morse code, traffic signs, semaphore flags, and more. Most languages include a spoken component, but many languages have developed a written tradition in the past 6,000 years, especially in the last 2,000 years. Since written language is a fairly recent innovation, given humanity's long history, it offers limited insight into the patterns of human migrations in the distant past.

Spoken language, which has arguably been around as long as modern humans, poses its own set of challenges. It precedes written language, which makes it difficult, if not impossible, to determine when and where individual words were used by the speakers of a language.

To make up for the lack of written records, linguists compare the sounds of fundamental words that have similar meanings—words such as “sky” or “dog” as opposed to “dendrochronology” or “gastroenterologist”—among two or more languages using what is called the comparative method. Words with a similar sound (phonetic) structure are more likely to have been

derived from a common ancestor; in linguistic terms, they are more likely to be cognates. Linguists can use the comparative method to reconstruct a protolanguage, for example, an ancestral language to today's modern tongues. Other approaches used to compare languages, such as lexicostatistics, take advantage of cognates or other similar terms but are not useful for the reconstruction of protolanguages.

Any method to compare languages faces a major problem in that languages may share basic words for reasons other than common descent. Speakers of one language may borrow a word from another language. Consider a modern example: Indonesians use the term *taksi* to describe a vehicle that can be hired to transport passengers around cities. *Taksi* is similar to the English word "taxi," used to describe a similar vehicle, but the similarities do not result from descent from a distant ancestor. Instead, it is a result of the Indonesians borrowing the term from modern English. Rigorous analysis can often reveal which words are true cognates and which are not.

At present, most languages are classified into a series of language families—all languages descended from a common ancestor. The language families are further subdivided into branches. The branches are likewise subdivided into groups. Language groups have the most recent origin; families have the most ancient origin. The largest language families, ranked in terms of numbers of speakers, are Indo-European, Sino-Tibetan, Niger-Congo, Afro-Asiatic, and Austronesian. Indo-European is the predominant language family in Europe and West and South Asia. Sino-Tibetan is the primary language family in East Asia. Niger-Congo is the dominant language family in sub-Saharan Africa, while Afro-Asiatic is the dominant family in North Africa and Southwest Asia. Austronesian is the primary indigenous language family of Madagascar, insular Southeast Asia, and Oceania.

Other language families that were either more widespread or encompass a large number of individual languages include Dravidian, found in South Asia; Altaic in Asia (some argue that Altaic should be split into two families, Turkic and Japonic); Austro-Asiatic and Tai-Kadai in main-

land Southeast Asia; Uralic in northern Eurasia; Eskimo-Aleut in the Arctic; Algic, Cariban, Maipurean, Mayan, Na-Dené, Pano-Tacanan, Quechuan, Tupian, and Uto-Aztecan in the Americas; and Nilo-Saharan and Khoisan in Africa.

While linguistic comparisons are of interest in better understanding the development of modern languages, such studies may benefit research on the history of human migrations, complementing research in paleoanthropology, archaeology, and genetics.

In order to reconstruct human migrations from language data, linguists make two major assumptions: that related languages share the same area of origin and that the best explanation of the current distribution of related languages is one that requires the least number of moves from their area of origin. The latter assumption is in keeping with the scientific principle of parsimony in which the simplest explanation for a set of phenomena is generally the best. Given that the place of origin of a group of related languages is often unknown, the simplest way to locate it is to mark the center of distribution of each of the related languages, then find the point that minimizes the distance between it and each of those centers.

In an ideal scenario, comparisons of migration patterns obtained from linguistic data, genetic data, and archaeological and anthropological data will coincide. For example, many scholars believe that there are four possible routes by which modern humans colonized temperate Eurasia: along the Pacific Coast from tropical Southeast Asia, up river valleys from southern China, from the Nile through the Fertile Crescent and Caucasus region, and from South Asia northward across the mountainous spine of Asia.

An apparent convergence of linguistic and other data seem to support substantial migration along three of these paths: the river route from southern China by the ancestors of Native Americans; the Pacific coastal route by the ancestors of people whose native languages fall within language families that include Indo-European, Uralic, Altaic, and Eskimo-Aleut languages; and a more recent migration of Afro-Asiatic speakers along the Nile-Fertile

Crescent-Caucasus route. Much more work on this matter remains to be done.

■ Introduction: What Causes Climate Change?

As the international community debates at the dawn of a new millennium what to do in the face of human-caused climate change, one fact is often overlooked in public pronouncements and media reports: one constant about climate is that it always changes. For most of earth's history, climate changes have been driven by natural processes, but humans, through their ability to modify the environment, have become an increasingly important force driving climate change.

Since the earth's climate system is powered by radiation from the sun, the sun is among the first culprits to be evaluated in suspected cases of climate change. The intensity of solar radiation reaching the earth has varied over time. These variations can stem from differences in

the amount of radiation emitted by the sun as well as from changes in the relationship between the earth and sun.

Since the origin of the solar system, the sun has grown brighter, and its radiation output has increased. Such a long-term process, however, is not likely to have played much of a role in triggering the many climate upheavals in earth's history. The sun's radiation output fluctuates regularly in keeping with cycles such as the 11-year sunspot cycle. The role of these cycles in triggering climate change is controversial.

The notion that variations in earth's orbit around the sun affect the intensity of solar radiation at the earth's surface is not controversial, however. The closer the earth is to the sun, the more intense the radiation and vice versa. The degree of tilt of the earth's axis affects the distribution of radiation on the surface. Ice ages may be more likely to form when the degree of tilt is at its least. These and other orbital characteristics change in a cyclical fashion. The cycles, called Milankovitch cycles, explain some of the major fluctuations in earth's climate—such as the ice ages—during the past few million years.

Atmospheric and oceanic circulation patterns are tightly linked; in fact, ocean currents play a major role in redistributing heat from the tropics, where there is a surplus of solar energy, to the poles, where there is a deficit of solar energy. The Gulf Stream, for example, a current that runs roughly northeastward across the Atlantic Ocean from Florida to the British Isles, helps moderate temperatures in Western Eu-

Global temperature, as measured by ratios of oxygen isotopes in deep sea and ice cores, has undergone a steady average decrease in the last five million years and is marked by huge fluctuations. This cooling is attributed to the onset of the glacial epoch some three million years ago. (Illustration by Jeff Dixon)

rope. The continent would be much colder without the current's influence.

Oceanic circulation can be altered by tectonic processes, as drifting continents affect the exchange of water between ocean basins. Surface currents, such as the Gulf Stream, are linked to deep, cold currents via what is called thermohaline circulation. This circulation is driven by changes in salinity and temperature of surface waters. These changes alter density of the water, triggering sinking of denser (colder and/or saltier) water masses and uplift of less dense (warmer and/or fresher) water masses.

Changes to thermohaline circulation can alter the strength and path of ocean currents and thus climate. For example, freshening of surface waters in the North Atlantic (where cold, salty, dense water typically sinks) by the melting of the Greenland ice pack can displace the Gulf Stream to the south, leading to a rapid, dramatic cooling of the climate in the North Atlantic basin.

Changes in earth's surface characteristics can also trigger climate change. An important influence of temperature is the amount of solar radiation absorbed. Absorption is driven by the albedo—reflectivity—of the surface. Reflective surfaces, such as snow and ice, reflect most solar energy, leading to lower temperatures (and more snow and ice). Open water and dark forested surfaces absorb most solar radiation, leading to higher temperatures (and less snow and ice). More than 600 million years ago, much of the surface was frozen over during a period termed the "Snowball Earth." The frozen temperatures made it almost impossible for life to exist at the earth's surface.

Many scientists believe that the snowball melted as a result of a change in the chemistry of the atmosphere. Massive release of greenhouse gases—gases such as carbon dioxide or methane that, like a blanket, trap solar heat near the surface—triggered a warming climate. Natural sources of greenhouse gases include volcanoes, wetlands, and some marine deposits. In recent decades, humans have likely been triggering a new round of climatic warming, however, by burning fossil fuels, leading to a buildup of carbon dioxide in the atmosphere.

Geological Epochs and Climate

Epochs are divisions of the geologic time scale that are the usual focal point for discussions of the environments of the past 65 million years. The geologic time scale is used by many earth scientists to organize analysis of and comparisons between events in the history of the earth. The largest subdivisions of the scale are eons, which range from 540 million years long (the duration of the current eon, the Phanerozoic) to 2 billion years (the Proterozoic). Eons are further subdivided into eras, which can range up to nearly one billion years long. The Phanerozoic includes the Paleozoic, Mesozoic, and Cenozoic (current) eras.

Eras are subdivided into periods that may be several hundred million years long. Dinosaur fans are familiar with the three periods of the Mesozoic: the Triassic, Jurassic, and Cretaceous. The Cenozoic includes two, the Paleogene and Neogene, the latter of which covers the past 23 million years. Periods are further subdivided into epochs for the Cenozoic. The Paleogene (65 million years ago to 23 million years ago) is subdivided into the Paleocene (oldest), Eocene, and Oligocene epochs. The Neogene is subdivided into the Miocene Pliocene, Pleistocene, and Holocene (current) epochs.

At the dawn of the Paleocene, life on earth was recovering from a massive extinction event that led to, among other things, the demise of the dinosaurs. As a result of continental drift, most of the continents were shifting northward. North America and Europe began to separate. These movements altered atmospheric and oceanic circulation patterns and, in turn, global climate. Oceans were warm, even at the poles, whereas climates began to cool over land areas

near the poles. Elsewhere, however, warm climates prevailed over land.

A massive warming took place at the Paleocene/Eocene transition about 55 million years ago. This warming, called the Paleocene-Eocene Thermal Maximum, is believed to have been triggered by a massive release of methane—a potent greenhouse gas—from marine sediments. A major increase in atmospheric carbon, whether in the form of carbon dioxide or methane, in the atmosphere would result in the acidification of the oceans. Widespread evidence for such acidification has been found in deep-sea sediments.

During the Eocene, North America completed its separation from Europe, South America moved farther from Africa, and Africa closed in on Europe. India was well on in its tectonic sprint from Antarctica toward Asia. Global temperatures remained relatively warm throughout the Eocene. The Eocene/Oligocene transition (39 million years ago) is marked by a major extinction event triggered possibly by meteorite impacts in Siberia or another near what is now the mouth of the Chesapeake Bay. While still

warm, the global climate began a slow cooling. This decrease in temperature was driven in part by the breakup of the southern continents, leading to the isolation of Antarctica and the cooling of the polar currents that now flowed freely around it.

The opening epoch of the Neogene—the Miocene, which began about 23 million years ago—was marked by a warming that rivaled the conditions of the Oligocene. That warm period came to a sudden halt about 14 million years ago at the Middle Miocene Climate Transition. Another major decrease in temperature began about eight million years ago as the Antarctic ice sheet began to reach its current size. Glaciers may have begun their expansion over Greenland at this time.

Antarctica was entirely ice-bound by the beginning of the Pliocene (five million years ago). At the other end of the earth in the Arctic, isotopic evidence and evidence of ice-rafted debris indicate that an ice cap had formed in the oceans of the far north. As the poles cooled, the climate of the middle latitudes became similar to that of

today, colder, drier, and more seasonal than in previous epochs. There is evidence of glaciation in the middle latitudes toward the end of the Pliocene.

The Pleistocene began about two million years ago with the continents more or less in their modern positions. The climate of the Pleistocene is dominated by several cycles of the advance and retreat of continental and alpine glaciers worldwide. Periods of advance are referred to as glacials; periods of retreat are referred to as interglacials. Four major glacials are recognized in North America—the Nebraskan (older), Kansan, Illinoian, and Wisconsinan (more recent)—but it is difficult to get an accurate number because evidence of older glacial advances is often destroyed during later ones. At their greatest extent, continental glaciers in the Northern Hemisphere reached to within 40 degrees of latitude of the equator. As the glaciers grew and locked up vast amounts of water, the seas retreated; sea levels were as much as 300 feet lower than today. During this epoch, modern humans evolved and spread across the planet.

The current epoch, the Holocene, began about 11,000 years ago as the last of the Pleistocene ice sheets retreated. Even though the climate of the Holocene is warmer than the Pleistocene, there were significant fluctuations. The earliest human civilizations were established and flourished during the Holocene climatic optimum (9,000–5,000 years before the present), when temperatures were as much as 4 degrees Fahrenheit (–15.5 degrees Celsius) higher than now. Cooler conditions, with a minor glaciation, prevailed until about 2,000 years ago. Since then, with minor variations, climate conditions have been much as they are at present.

Global Climate of the Pliocene

The Pliocene (5 million to 1.8 million years ago) is an important time in earth's climatic history. It was a period of transition from the warmth of the Miocene to the cold of the Pleistocene. Despite the overall cooling that took place during the epoch, a prolonged span of warm temperatures—the Pliocene Warm period, from 4.5 million to 3 million years ago—interrupted the cooling trend.

As the Pliocene began, earth's climate was nearing the end of a cooling that began in the Middle Miocene. The Antarctic ice sheets were expanding, and ice had been spreading across the Arctic region.

The expansion of the ice-bound realms stopped during the Pliocene Warm period. Global average temperatures rose to about 5 degrees Fahrenheit (–15 degrees Celsius) warmer than today, with even greater amounts of warming in high-latitude regions. Sea levels were 30 feet to 60 feet higher than present. The polar ice caps shrank somewhat.

While the cause of the Pliocene Warm period is not known, evidence indicates that El Niño-like conditions prevailed throughout much of the period. Under typical conditions, sea-surface temperatures in the eastern equatorial Pacific are cold, whereas in the central and western Pacific they are warm. Winds near the surface generally blow from the east to the west. In an El Niño, the sea-surface temperature differences are weakened, or else the temperature patterns are reversed. Equatorial winds likewise weaken or blow in the opposite direction. In the twenty-first century, El Niño events can have catastrophic effects on global weather patterns. Sustained El Niño conditions during the Pliocene Warm period could likewise have had dramatic effects on climate then.

By about three million years ago, an increase in Northern Hemisphere glaciation heralded the end of the warm interval and the start of a long-term cooling trend. Steps in the cooling process took place at different times in different regions. A host of factors may have contributed to the cooling.

In conjunction with cooler temperatures, drier conditions spread over many regions, leading to a decline in the distribution of tropical

forests and expansion of grasslands and temperate forests. A number of large grazing mammals—species capable of living off the grasses that spread across the landscape—appeared during this time, as did *Homo habilis*, an ancestor of modern humans.

Global Climate of the Pleistocene (Quaternary)

The Pleistocene is arguably one of the most dramatic epochs in earth's past and one of the most important in the development of modern humans. Characterized by several cycles of advance and retreat of vast continental ice sheets, the interval is often referred to as the "Ice Age."

In older versions of the geologic time scale, the Pleistocene was grouped with the current epoch, the Holocene, into the second of two periods of the Cenozoic era: the Quaternary. The status of the Quaternary is controversial. Proposals range from treating the Quaternary as a period in its own right (equal status with Neogene and Paleogene) to retaining it as a named portion of the Neogene and to scrapping the term altogether. Many scientists feel that the Quaternary should begin with the Gelasian stage (the uppermost stage of the Pliocene epoch) about 2.6 million years ago and include all of the Pleistocene and Holocene epochs. The Quaternary was demoted to a subera in the most recent revision of the Geologic Times Scale, but many Quaternary scientists are unhappy with the decision. Thus, the matter remains under debate.

The argument for lumping the Gelasian stage with the Pleistocene epoch centers on the cli-

mate; for the past 2.6 million years, the earth has undergone several cycles of glacial advance and retreat. These cycles began with major glaciation in the Northern Hemisphere during the Gelasian as indicated by ice-rafted debris—rocky material carried by icebergs—in the North Atlantic and North Pacific. The cooling trend that began in high-latitude regions spread to the subtropics and tropics, a pattern similar to that of later glaciations.

Pleistocene terminology can be somewhat confusing, as American researchers and European researchers differ somewhat in usage. According to North American usage, a glaciation (glacial) is a period of major ice advance and retreat. An interglaciation (interglacial) is a period in which climate did not favor widespread glaciation. Glaciations can be further subdivided into stadials, or periods of minor ice advance, and interstadials, or periods of minor ice retreat and/or lack of movement in either direction.

Another source of confusion regards the number of glacial periods. Glaciers act as bulldozers, scouring the landscape in many cases down to bedrock. This process destroys evidence of previous advances, leaving geologists with the task of reconstructing glacial chronologies from fragmentary evidence along the fringes of the former ice sheets. Geologists often turn to marine sediments to help clarify the chronologies, but differences between marine and land-based evidence lead to further challenges in correlating data.

For example, land-based evidence indicates four major glaciations in North America during the Pleistocene: the Nebraskan (older), Kansan, Illinoian, and Wisconsinan (more recent). For Europe, however, up to six are recognized: Biber, Donau, Günz, Mindel, Riss, and Würm. Marine evidence, however, indicates dozens of potential Pleistocene glaciations.

Temperature patterns during interglacials were typically as warm as or warmer than today. During glacial periods, high-latitude temperatures could be significantly colder, especially in the neighborhood of the great ice sheets where high reflectivity and heat absorption by the ice led to cooler conditions. Glaciers could also exert significant influence on atmospheric circulation patterns.

THE GREAT ICE AGES

Ice ages refer to several periods in the earth's past when the global climate cooled and glaciers advanced from polar and subpolar regions into the middle latitudes. While the term "ice ages" is typically used to describe several glacials (periods of glacial advance) during the Pleistocene epoch (1.6 million to 10,000 years ago), there were several other ice ages in the earth's past, and some of the earlier ones were even more extensive than those of the Pleistocene.

Past ice ages include the Karoo (350 million–250 million years ago) during the Carboniferous and early Permian periods, the Andean-Saharan (450 million–420 million years ago) during the Ordovician, the Cryogenian (800 million–600 million years ago), and the Huronian (2.4 billion to 2.1 billion years ago) during the Proterozoic. The Cryogenian Ice Age was arguably the most severe ice age, for evidence shows that glaciers as well as sea ice may have extended into the equatorial zone. Because of the hypothesized extent of ice, this time has been referred to as the Snowball period.

Temperatures in tropical regions stayed relatively warm, although there is evidence of a tremendous reduction in the areal extent of the Amazon rain forest during the Kansan glaciation, likely triggered by cooling in tropical latitudes. Regions that are now quite arid—such as the southwestern United States or portions of North Africa—were often quite a bit wetter, resulting in the expansion of ecosystems like grasslands and forests in places that are now desert. Great glacial lakes formed in places where ice and glacial debris formed dams behind which rainwater and meltwater accumulated.

The ice dams posed another climate-related hazard: flooding. The waters of Glacial Lake Missoula, for example, which covered portions of the northern Rocky Mountain region in what is now Idaho and western Montana, periodically spilled down what is now the Columbia River basin in cataclysmic floods when the ice dams failed. These floods created the Channeled Scablands in eastern Washington. While floods could drain glacial lakes, they could also create lakes

Evidence for recent glaciation—within either the Pleistocene epoch or the Holocene, which followed—abounds in the surviving continental and alpine glaciers today as well as in glacially generated landforms such as arêtes, cirques, drumlins, eskers, and fjords. Evidence for older glaciations is not as widespread; the evidence often consists of deposits of tillite, a rock made of boulders and sorted and unsorted glacial deposits that have been buried and cemented into solid rock.

Ice ages may be triggered by a number of factors. One is the relationship of the earth to the sun. The orbit is not at a constant distance, and the elliptical path that the earth follows alternately lengthens and shortens. As the earth moves farther from the sun, the radiation it receives is less intense than when the earth is closer. Over long periods the climate can cool down, and glaciers begin to advance. Other factors, such as change in distribution of land and water as a result of continental drift and changes in atmospheric composition, may also play a role in initiating or ending glacial periods.

—David M. Lawrence

by filling basins that either existed before or were gouged out by the ice sheets.

The flow, or lack thereof, of meltwater into ocean basins affected climate far from glaciated areas by disrupting the thermohaline circulation, a global heat exchange engine driven by changes in the temperature and salinity, hence density, of seawater. Changes in the thermohaline circulation disrupt surface currents, such as the Gulf Stream, and can either enhance or retard upwelling of cold, deep waters, such as off the northwest coast of South America. These changes altered atmospheric temperature and pressure patterns, which in turn affected atmospheric circulation.

Global Climate of the Holocene

The Holocene, which began about 11,000 years ago, is the fourth and last epoch of the Neogene, the latest period in the Geologic Time Scale. The Holocene, formerly known as the Recent, began about 11,000 years ago as the last of the Wisconsinan (in North America) ice sheets retreated. It is part of the controversial subera known as the Quaternary, the status of which is currently being debated by the scientific community.

The Holocene is important for a number of reasons, the primary one being that human civilization arose during the relatively mild climate of the epoch. The importance of civilization is reflected in the typical subdivisions of the Holo-

cene. Epochs are typically subdivided on the basis of characteristic groups of animal and plant fossils. But the Holocene is often subdivided on the basis of stages in the development of human technology using terms such as Mesolithic (during which animals and plants were domesticated and agriculture began) and Neolithic (during which permanent agricultural settlements and crafts such as pottery and weaving originated).

The Holocene originated as the Younger Dryas, a cold period at the end of the Pleistocene, waned. As the climate warmed during the Holocene Thermal Maximum (Holocene Climate Optimum, about 11,000–5,000 years before the present), the glaciers that had gripped much of the midlatitudes retreated toward the poles or back toward higher elevations. Forests and grasslands expanded northward into areas vacated by the ice. The timing of the warming—as much as 8 degrees Fahrenheit (–13.3 degrees Celsius) in some regions—varied, with delays in areas where ice sheets such as the Laurentide Ice Sheet (centered in what is now Quebec and Labrador) lingered.

This warmth was interrupted briefly about 8,200 years ago by a rapid cooling triggered

► GREENLAND ICE CORES

Ice cores from the glaciers of Greenland offer a proxy climate record that extends back in time for tens of thousands of years. While Antarctica similarly offers long-term ice core records, the Greenland cores are especially important because they record climate fluctuations in the Northern Hemisphere, where most of humanity is found.

Ice cores contain layers of snow and ice deposited over long periods of time. They are especially important to climate studies because, by trapping air bubbles, aerosols, dust, and volcanic ash inside the ice, they keep a sample of past atmospheres in cold storage until those samples can be retrieved and analyzed.

Scientists have been coring Greenland's glaciers for decades. Early drilling efforts obtained times series extending to about 40,000 years before the present. During the past two decades, however, several large-scale projects—the Green-

land Ice Sheet Project (GISP and GISP2), the Greenland Ice Core Project (GRIP), and the North Greenland Ice Core Project (NGRIP)—have obtained ice core records dating back to more than 100,000 years before the present.

The NGRIP core is one of the best, providing annual data on past climates for the past 120,000 years. Isotopic data from that core, which extended to more than 10,000 feet (3,048 meters) deep, shows that climate was warmer than today during the Eemian Interglacial (Warm) period. The Eemian climate was relatively stable, much like the climate has been the past 10,000 years during the Holocene. A brief warming period interrupted the onset of the last glacial (Ice Age) period. The latest glacial period has been punctuated by climate fluctuations (Dansgaard-Oeschger events) characterized by rapid warmings followed by periods of gradual cooling.

—David M. Lawrence

probably by a massive inflow of freshwater into the North Atlantic from melting ice sheets in the North Atlantic. The freshening of the North Atlantic likely disrupted the portion of the thermohaline circulation involving the Gulf Stream, which in turn altered atmospheric temperature and pressure patterns over wide areas of the earth. The event was of short duration, about 200 years.

During the time of the Holocene Thermal Maximum, northern and western Africa received more rainfall than today. This interval, known as the African Humid period, began late in the Pleistocene. It was triggered by strengthening of the West African monsoon. The Sahara, now the world's largest desert, was dotted with lakes, with woodlands and grasslands scattered throughout. Early human civilizations took root during this period. East Asia likewise was warmer and wetter during this period.

The seas were also affected by the warming of the climate as the Pleistocene ended and the Holocene began. Sea levels have risen by nearly 400 feet in the past 20,000 years. Vast areas of what were coastal plains were inundated, as were valleys that are now bays (such as the Chesapeake and Delaware bays). The Black Sea, formerly a depression kept relatively dry by an ice dam between it and the Mediterranean, was flooded about 7,500 years ago as the ice melted and the dam gave way. Such sea-level changes altered climate in coastal areas by changing local weather patterns; some may have had more widespread effects by modifying surface currents in the oceans.

Both the Holocene Thermal Maximum and the African Humid period came to an abrupt end about 5,200 years ago with rapidly cooling temperatures around the world and with increasing aridity in places like North Africa and the Arabian Peninsula. Neolithic settlements were abandoned in the Arabian interior, while highly structured societies developed in Egypt and Mesopotamia. It was at about this time that the famous Tyrolean Iceman—discovered in 1991 in the ice of a retreating glacier on the Austrian-Italian border—died and was quickly buried in the snow that concealed him for five millennia.

The global climate recovered somewhat within two or three centuries, but temperatures

did not return to Holocene Thermal Maximum levels. With cooler temperatures, glaciers again went on the advance, but the amount of area covered by glaciers was far smaller than that covered during peak periods of the Pleistocene.

The climate warmed again about 2,500 years ago; this warming culminated in the somewhat controversial Medieval Warm Period (about 800–1300 CE). The existence and extent of the Medieval Warm Period has become a contentious point in the climate change debate. The period, well documented in Europe and other parts of the North Atlantic basin, was assumed to have been a global phenomenon. Climate analyses, however, find warming in some places (such as Europe) but not in others. There is evidence for widespread precipitation anomalies, however, with some regions significantly wetter than normal, while others were significantly drier than normal.

The period that followed, however, is much less controversial: the Little Ice Age. A cooling trend that lasted until the mid-nineteenth century is evident from historical records and other data from around the world. A major feature of the Little Ice Age was the expansion of glaciers worldwide. A prominent casualty of the Little Ice Age was the Norse colony founded on Greenland during the Medieval Warm period. As the cold set in grasses and crops failed, and people who were unable to evacuate the colony starved.

Since the end of the Little Ice Age, average global temperatures have steadily warmed to levels higher than any point in the past millennium.

■ Introduction: The Human Family Lineage—8 Million Years Ago to 20,000 Years Ago

The human family lineage spans some eight million years of earth's history. Our lineage comprises not only our own species, *Homo sapiens*, and close relatives but also more distant relatives, attributed to different genera such as *Australopithecus* and *Paranthropus*. The farther we travel back into our history, the more different these relatives look, though they all share the peculiar characteristics that make us human. These typical human features are smaller canine teeth and an upright posture since the very beginning of our evolution. Our family tree is no direct, linear progression, starting from a primitive apelike form and ending with us, but is bushlike instead, with many dead-ending branches. Our tree is as diverse as that of the lineages of other mammalian species. Throughout this branching bush, three clear trends characterize our family line: first, the development of bipedalism; second, an increase in brain size; and finally, a gradual change in the dentition.

The origin of the human family lineage can be traced back to the Late Miocene. In sub-Saharan Chad in Africa, a skull of *Sabelanthropus tchadensis*, referred to as "Toumai," meaning "hope of life," was found in geological strata six million to seven million years old in 2001. The skull of "Toumai" is small, has a very small brain cavity (estimates of 320–380 cubic centimeters), and resembles the skull of a chimpanzee. Yet the skull also has humanlike features (the foramen magnum is positioned forward and oriented downward) and is therefore considered by some scientists to be an early hominine, not an ape.

The next in the human family line might be *Orrorin* (meaning "original man") *tugenensis*, found by Cheboi in 2000 in the Tugen Hills of Kenya by a French-Kenyan team in strata dated between 5.27 million and 5.88 million or 6.2 million and 5.65 million years ago. Though the remains of this species are scanty, they show some typical hominid features, like thick enamel on the teeth and thigh and shin bones that indicate an upright posture, according to the discoverers.

The findings of *Orrorin* are of more or less the same geological age as those of *Ardipithecus ramidus*, found in Ethiopia in rocks dated between 5.2 million and 5.8 million years ago. The genus is based on fossils found in 1992 and 1993 by Tim White and his team. The remains are nothing more than many fragments, yet they are conclusive enough to attribute this species to our lineage. The arm and forearm bones seem to show a number of features that suggest a four-legged ground-moving ape. Its canine teeth are reduced in size like ours, and the lower jaw is more V-shaped, as is typical for the human lineage, whereas the apes have a more U-shaped jaw.

By 4.2 million years ago, the members of the human lineage are more advanced than the Miocene forms and begin to resemble us more. Although *Australopithecus* is more advanced than previous members, it is still very apelike in having a prognathic, or projecting, jaw; a small brain; and a small stature. Several species are known, of which the earliest known is *Australopithecus anamensis*, found in rocks near Lake Turkana in Kenya ranging from about 3.9 million to 4.2 million years ago. The next species in time is *Australopithecus afarensis*, better known as "Lucy," found near Hadar in Ethiopia in 1973 and published in 1978 as a new species. *Australopithecus afarensis* lived between 3.9 million and 2.7 million years ago and left a famous trackway near Laetoli in Tanzania, from which their way of walking can be inferred. The trail was made by two adult humans and a child, likely all three walking upright. Another famous *afarensis* fossil is the three-year-old girl, known as "Baby Lucy" or "Selam," found in 2000 at Dikika in Ethiopia. Younger in geological age are *Australopithecus bahrelghazali* from Chad of 3 million to 3.5 million years ago, *Australopithecus garhi* of 2.6 million years ago, and *Australopithecus africanus* of 2.8 million to 2.4 million years ago. The last species is based upon the skull of a child, known as the "Taung baby" after the Taung limestone quarry from which it was recovered by Raymond Dart in 1924. Later, be-

tween 1936 and 1948, Robert Broom found remains of adults in South African caves (Sterkfontein, Kromdraai, Swartkrans) and also by Dart (Makapansgat). Important findings are an adult skull known as “Mrs. Ples” (first indicated as *Plesianthropus transvalensis*) with attributed skeletal parts from Sterkfontein.

Australopithecus africanus is a small and gracile form with a small brain and small cheek teeth and lacking a skull crest. It differs essentially from a group of other *australopithecines*, which are robust. They have large cheek teeth, dish-shaped faces due to wide and flaring cheek bones, and a prominent skull crest as an adaptation to a vegetarian diet consisting of nuts and seeds. These robust australopithecines (*A. aethiopicus* between 2.3 million and 2.8 million years ago, *A. boisei* of 1.8 million to 1.4 million years ago, and *A. robustus* of 1.8 million to 1.0 million years ago) are often attributed to a genus of their own: *Paranthropus*. The earliest of these robust forms, *A. aethiopicus*, is known from a male skull, the “Black Skull,” discovered in 1975 on the shores of West Lake Turkana in Kenya. This species is considered the most primitive of the robust lineage. *A. boisei* is the most robust and is known as “Nutcracker Man” because of its huge thick-enameled molars, massive jaws, and strong skull crest. It was found in 1959 by Mary Leakey at Olduvai Gorge in Tanzania. A third species, *A. robustus*, was discovered in 1938 at Kromdraai cave in South Africa. Later, similar remains were found in other South African caves. There is some controversy as to whether *A. boisei* and *A. robustus* should be considered as a single species, but most paleoanthropologists today place them in closely related, but separate, lineages.

During the same period in which *Australopithecus* lived, another more primitive form of the human lineage lived in Africa, *Kenyapithecus platyops*. Its fossils were found in 1998 and 1999 in Kenya in strata dated to 3.5 million years ago. There are no known skeletal bones for *Kenyanthropus* (meaning “Man of Kenya”).

The first member of our genus is *Homo habilis*. It shared with us a larger brain size, a flatter face, small cheek teeth, and reduced canine teeth. It also lacks a skull crest and has reduced brow ridges, giving it a more gracile appearance. It is not clear which of the australopithecines

The hominin phylogeny. Lines linking the branches are not included because many of the relationships between the species remain unclear. (Illustration by Jeff Dixon)

could be the ancestor of *Homo*, but generally a form like the gracile *A. africanus* is considered the most likely ancestor. *Homo habilis* was discovered in 1960 in Olduvai Gorge in Tanzania by Mary Leakey in sediments of about 1.75 million years ago. Not only bones have been found; in Koobi Fora in East Turkana in Kenya an ancient camping site has been discovered where *Homo habilis* had camped about 1.8 million years ago around the carcass of a hippopotamus. They removed bones, meat, and marrow from the carcass with the use of small stone flakes, which they brought there from some 12.4 miles (20 kilometers) away. Similar places are found in Olduvai, once a shallow lake where hominids and animals came to drink. Another early *Homo* species is *Homo rudolfensis* of 2.4 million to 1.9 million years ago. No tools are found with this species. Both species, based on long arms, short legs, and small brain, are attributed by some scientists to *Australopithecus*.

Homo ergaster lived between 1.8 million and 1.6 million years ago. This human species is represented by a nearly complete skeleton, known as “Nariokotome Boy,” found on the shores of West Lake Turkana in Kenya in 1984. He was particularly tall, as the full-grown length of Nariokotome Boy is estimated at 5.9 feet (1.8 meters). *Homo ergaster* is often considered the African *Homo erectus*.

These early *Homo* species are generally considered to have made primitive stone tools,

choppers, and hand axes of the “Olduvai” culture, named after the Olduvai Gorge where these simple stone flakes were first recognized. This primitive technique, according to which the toolmaker stroked off a flake with a hammer stone, has been replicated by Nicolas Toth in the early 1980s. The tools were fit for splitting hide, cutting up a carcass, and breaking open bones for their marrow but not for hunting. Therefore, it is suggested that *Homo habilis* was at most a scavenger.

The main differences between members of the new genus *Homo* and *Australopithecus* are a much increased body and brain size; smaller teeth and, in accordance with that, a less-protruding face; and a striding gait. It is generally believed that these changes were induced by an increased complexity of human social interactions combined with a more varied diet. Life in a food-sharing social group places more acute demands on the ability to cope with unexpected situations and make fast decisions. The increased complexity of the social interactions was the main drive behind the development of a large brain, whereas the variegated diet, partly made easy to digest by food handling (smashing, grinding, cooking), was the main drive behind the regression of teeth size.

At about the same time a fourth *Homo* species arose, *H. erectus*. This species had an even larger brain but somewhat smaller in size than that of our own species. The stone tools made by *Homo erectus* belong to the “Acheulian culture.” *Homo erectus* was the first human species to leave Africa and colonize Eurasia. The earliest fossils of *Homo erectus* in Asia are dated to 1.8 million years ago and are found at Dmanisi in the modern Republic of Georgia. *Homo erectus* fossils from Java Mojokerto and Trinil (“Java Man”) are dated to 1.2 million years ago. Younger *Homo erectus* fossils, dated to between about 830,000 and 240,000 years ago, are found at several sites in Java and China (“Peking Man”), at Tham Khuyen in Vietnam, and in the Narmada Valley of India (“Narmada Man”). The last occurrence of *Homo erectus* in Asia is on Java 200,000 years ago. In Europe, possibly also in Africa and China, another species developed (*Homo heidelbergensis*) between 500,000 and 200,000 years ago. This form is more robust than *Homo*

erectus and is considered the ancestor of Neanderthals. The earliest Europeans (*Homo antecessor*) of Spain of 800,000 years ago may represent forerunners of *Homo heidelbergensis* or descendants of *Homo erectus* or may be unrelated to these species.

Neanderthal fossils were the first human fossils to be discovered. In 1856, quarry workers found a skeleton in a limestone cave in the Neander Valley near Düsseldorf in Germany. Although some scholars of the era correctly recognized the remains as those of a robust and ancient race, others concluded that their Neanderthal Man suffered from hydrocephaly or rickets. The image of the Neanderthals did not improve much after scientific acceptance, because the first descriptions were based on the skeleton of a diseased old man from Chappelle-aux-Saints in France, known as the “Old Man.” For decades this species was depicted as a primitive hairy creature with a crooked back, which lay the basis for persistent erroneous image of cave people in general.

In reality, however, Neanderthals had a slightly larger brain than us, a robust and strong body, and a complex culture with stone tools of the “Mousterian culture,” which enabled them to hunt even mammoths. Their skull resembles that of *Homo erectus* with large brow ridges, no chin, and a protruding face. Neanderthals were typically adapted to a life in cold climates, which may explain their robust and short stature. For decades Neanderthals were considered to be a subspecies of our species, but at present they are attributed to a species on their own, *Homo neanderthalensis*, based upon DNA and skull morphology.

Neanderthals lived in Europe and the Near East between 100,000 and 30,000 years ago. The reason behind their extinction is not well understood; possibilities that have been raised are a climate change, a dramatic conflict with modern humans (replacement model), a disease introduced by modern humans, a gradual evolution into modern humans (multiregional model), or an absorption into the modern human population (interaction with Cro-Magnon).

About 200,000 years ago, the last species of our lineage made its entrance in the fossil record of Africa. The earliest remains of an archaic

Homo sapiens are known from Herto in Ethiopia and date to 195,000 years ago. *Homo sapiens* left Africa at about 150,000 years ago and entered Eurasia, South Asia, and Southeast Asia. *Homo sapiens* coexisted with the Neanderthals for almost 10,000 years. After the extinction of the last Neanderthals, *Homo sapiens* was practically the only living species of our lineage. Only on Flores Island in Indonesia a relict population of another human species survived, *Homo floresiensis*, nicknamed the “Hobbit” because of its small stature. The origin of this species is not yet resolved, but they are either descendants of *Homo erectus* or a local form of *Homo sapiens*.

During its history, *Homo sapiens* developed complex cultures, characterized by the use and making of derived tools and weapons, the invention of art, and the performance of religious ceremonies. The best-known examples of early *Homo sapiens* are the Cro-Magnon people in Europe, who are responsible for the cave paintings.

Our Most Ancient Ancestors— Eight Million to Five Million Years Ago

Humans are descended from ancestors shared with all the living apes on the planet. These ancestors thrived during the Miocene epoch, from 23 million to 5 million years ago, in Africa, Europe, and Asia. Humans stop sharing ancestors with the other apes between eight million and five million years ago, when the ancestors for each of the African great apes branched off on their own. First gorillas split off at about eight million years ago, then at about six million years ago chimpanzees and humans share their last common ancestor before they go their separate

ways. Thus, although gorillas may look and behave more like chimpanzees than we do, they are not as closely related to chimpanzees as we are. This part of our evolutionary history is recorded better in our genes than in the current fossil record (e.g., *Sabelanthropus*, *Orrorin*, and *Ardipithecus*), but paleoanthropologists are constantly finding more fossil evidence to put this story together and to test the genetic hypotheses.

During the Miocene, the world was a hot, wet place with vastly more geography dedicated to rain forests than today. For example, apes were able to live up into central Europe where the environment is too cold to support them now but where, in the Miocene, they had densely wooded forests replete with ripe fruit sources. This veritable planet of the apes held the right environmental conditions for the evolution of complex ape cognition and sociality that laid the evolutionary groundwork for our own.

Based on genetic similarities between living species and by estimating the time that it took to accumulate the differences they contain in their DNA, molecular clocks point to a divergence between apes (hominoids), including humans, and Old World monkeys (cercopithecoids) at the beginning of the Miocene, at about 23 million years ago. Then the lineage that gave rise to the so-called lesser apes, gibbons and hylobatids of China and Southeast Asia, split at about 18 million years ago.

The fossil record confirms these hypotheses. Sediments from the early Miocene of East Africa have produced the oldest fossils of primitive apes. A well-known creature of this sort, *Proconsul*, hails from sites in Kenya and Uganda. Dating to about 18 million years ago, the *Proconsul* skull and the teeth resemble apes, but most of the skeleton looks primitive and monkeylike, with some species as small-bodied as rhesus macaque monkeys (about 30 pounds or 13.61 kilograms). Small apes, like the size of modern gibbons and siamangs, are prevalent in the Early Miocene primate fossil record. Decades ago, *Proconsul* and the now-defunct taxon *Ramapithecus* (whose fossils have been assigned to other fossil ape species) were initially thought to be protohumans and potentially even bipedal. Now, however, the current fossil and genetic evidence tells us that protohumans did not appear

until much later, at end of the Miocene after the evolution of the great apes.

Much like the fossil record for our split from the monkey lineage at the beginning of the Miocene, the fossil record for the diversification of great apes in Africa, including humans, at the end of the Miocene is still somewhat patchy and difficult to interpret. However, the recent discovery of new specimens has provided some hope that the evolutionary history of gorillas, chimpanzees, and the earliest humans will eventually be resolved. Part of what makes reconstructing great ape evolution difficult is that most of the great specimens are actually found in Europe. *Dryopithecus*, *Pierolapithecus*, and *Ouranopithecus* are just a few examples of European fossil apes, represented by beautiful teeth, skulls, and skeletons, that all share traits with living great apes. It is possible that African great apes evolved in Europe or Asia after the initial evolution of the entire lineage in Africa. However, since there is a somewhat constant fossil record in East Africa for ape evolution, and given that gorillas, chimpanzees, and humans live there now, the simplest explanation is that they evolved in Africa.

Chororapithecus from about 10.5 million to 10 million years ago in Ethiopia, *Nakalipithecus* from about 9.9 million years ago in Kenya, and *Samburupithecus* from about 9.6 million years ago also in Kenya are all candidates for African great ape ancestors. Most of these traits are identified in the teeth, and these apes, which like modern ones, were designed for eating tough, hard fruits and vegetation. Because they are also large-bodied like modern apes, they probably foraged terrestrially for a greater proportion of their day than their more arboreal ancestors.

Beyond these Late Miocene apes, there is a continuation of the fossil record for neither gorilla evolution nor chimpanzees. After the Miocene, the only African apes on record are humans and our extinct ancestors, with one exception: a few 500,000-year-old fossil chimpanzee teeth from Kenya that look modern. It is probable that like modern apes, their ancestors were living in forested environments that are not well suited for sedimentation and fossil preservation. It is also possible that some of the fos-

sils from the Late Miocene and Early Pliocene that are currently labeled as hominins, or extinct bipedal human ancestors, are actually fossil chimpanzee and gorilla relatives instead.

These are some of the objections that researchers have made about the earliest hominins *Sabelanthropus*, *Orrorin*, and *Ardipithecus*, which are all placed on the earliest part of the strictly human branch of the ape family tree (i.e., the hominin branch). Some researchers consider that their assignment as hominins should be considered probationary until more specimens are discovered. Recent fossil humans, like those of the fossil chimpanzee teeth mentioned above, are not at all difficult to recognize; however, the farther one travels back in the fossil record toward the last common ancestor we share with chimpanzees, the fewer the available traits for distinguishing species.

Sabelanthropus from about 6 million years ago in Chad is currently the best candidate for earliest hominin, but *Orrorin* from about 6 million years ago in Kenya and *Ardipithecus* beginning around 5.8 million years ago in Ethiopia (and lasting for over 1 million years into the Pliocene) are nearly as old. Bipedalism is still the requirement that hominins must meet in order to be put firmly on the human line, but it appears that changes in teeth, like smaller canines and thicker enamel, are probably just as characteristic of our lineage and may have occurred concomitantly or even prior to the adoption of bipedalism. *Sabelanthropus* is represented by a cranium and jaws, so it is difficult to reconstruct locomotion, but the teeth and the face share similarities with later hominins. *Orrorin*, on the other hand, does have leg bones preserved, and the femur seems to indicate that it withstood the stresses unique to bipedal locomotion, but that interpretation is debated. The best earliest hominin fossils are of the genus *Ardipithecus*, which is represented by at least 40 individuals, most of which are single teeth but one of which is a well-preserved partial skeleton. Although the skull and teeth look like later hominins, the skeletal anatomy is still primitive and adapted to walking quadrupedally and climbing trees with a grasping big toe much like apes do. However, the pelvis shows some modifications that facilitated walking on two legs when on the ground.

It is possible that the long-held assumption that the evolution of bipedalism instigated the split between the lineage leading to humans from that leading to chimpanzees is incorrect and that an increase in tooth enamel thickness (for eating tougher foods) and a decrease in canine size (indicating its reduced use in social threats and displays) are all that distinguish early humans from early chimpanzees. Instead of new locomotor behavior, perhaps new dietary or social behaviors kick-started our evolution. This is just one of the issues that scientists will resolve with the discovery of more ape fossils from the Late Miocene.

The Late Miocene Climate and Environments of Central, Eastern, and Southern Africa

The Early and Middle Miocene African climate was wet and hot, and tropical rain forests covered major parts of the continent. In the Late Miocene, about 12 million to 5 million years ago, the African climate started to change dramatically as air flow and patterns of rainfall altered. The cause of the Late Miocene climate change was the development of the Great African Rift Valley, running from modern-day Israel to Mozambique. The Rift increased temperature contrasts and blocked moisture transport. On the west side of the Rift Valley the tropical forest was hardly influenced, but on the east side the

climate became drier. Toward the end of the Miocene, woodland savannas with grasses and weeds expanded farther in central, eastern, and southern Africa.

The African forests of the Late Miocene were still larger than those of today, while deserts and grasslands were smaller. The Sahara region was covered with grasslands. By the end of the Miocene, wet connections in the form of waterways of wetlands still existed between central and northern Africa, across the Sahara region, and between eastern and northern Africa, as evidenced by fossils of semiaquatic animals (*Libycosaurus* and *Kenyaipotamus*, respectively).

Rainfall patterns in eastern Africa are also related to the surface temperature of the Indian Ocean, which changes periodically. In wet phases, evaporated water from the Indian Ocean is transported mainly to eastern Asia but in dry phases to southern Asia. Plant fossils indicate that wet phases were still dominant at 12.6 million years ago and again around 6.8 million years ago. A dry phase existed at ten million years ago. At the Miocene-Pliocene boundary, the wet phase intensified temporarily due to the drying of the Mediterranean Sea, known as the Messinian event.

During the Pliocene at about 4.6 million years ago the dry phase would become dominant, resulting in the drier central and eastern Africa of today. Grasslands expanded at the cost of forests. The climate also became more seasonal. Seasonality means the end of tropical arboreal plants. On the interior plateau of southern Africa, woodland savannas arose. The present-day semiarid climate of southwestern Africa with rainfall in the winter was established somewhere in this period.

The cooling of the earth had begun already at the end of the Cretaceous period. The Late Miocene cooling was a late part of this global cooling. During the Late Miocene, life on earth became increasingly similar to that of today. The gradual spread of grasses and weeds and the reduction of forests reflected the global Miocene cooling of the earth. Toward the end of the Miocene, the Antarctic ice sheet was almost as large and thick as it is today. The continents had assumed more or less their present-day configuration.

As a direct result of the change in climatic and flora, a change in the fauna took place as well, with an explosion of grazing animals on the grasslands and savannas, and of primates in the thinner forests. The Late Miocene and the Early Pliocene are the time of success of our early ancestors. Without that Late Miocene climate change, we as a species may not have existed at all.

The Importance of *Sahelanthropus tchadensis*

In 2002 Michael Brunet and his team of researchers published an article in *Nature* titled “A New Hominid from the Upper Miocene of Chad, Central Africa.” This new specimen was named *Sahelanthropus tchadensis* (TM-266-01-60), or commonly Toumai, meaning “hope of life.” Unearthed at Toros-Menalla, a site in the Djurab Desert of Chad, the specimen consisted of a nearly complete cranium, two fragments of a lower jaw, and several teeth. Although no subcranial elements were found, these specimens displayed a mix of hominid and ape features previously unseen in paleoanthropology. While Brunet and his team lead the argument that *S. tchadensis* is the oldest hominid, skeptics claim that there is more evidence that this specimen is a Miocene ape. Others propose that the specimen is a failed species occurring during the divergence. Whether this specimen is a hominid, an ape, or a dead-end ancestor, its importance to anthropology is indisputable.

The location of the Toumai skull caused a stir among researchers for two main reasons. First, it is found in Chad, which is located in the middle of the African continent. During the Miocene era this area consisted of well-watered woodland. Prior to this finding, the majority of significant hominid excavations occurred in East and South Africa. If this skull is a hominid, then its discovery in central Africa reveals that early

hominids had a much wider range than earlier presumed. Second, the specimen was associated with fossil fauna that had been found at two East African sites. These fossils had been indisputably dated in the range of six million to seven million years ago. Although the geological context in which the Toumai skull was found did not allow for radiometric or paleomagnetic dating, comparison with these fossils would make Toumai the oldest hominid cranium ever found. This gives support to the genetic evidence that the hominid lineage diverged from the chimpanzee lineage during this time period. From DNA evidence, scientists have proposed that the split between the chimpanzee (*Pan troglodytes*) and hominid lineages occurred between five million and eight million years ago. This finding pushes the likelihood of this divergence having occurred closer to eight million than five million years ago. Prior to this discovery, the five million-year-old australopithecines were thought to have been the oldest ancestor of modern humans. Those who believe Toumai to be a hominid claim that its age will change how scientists view evolution.

At the center of the debate is whether or not Toumai was bipedal. This is fueled by the mixed hominid-ape features of the fossil. Brunet and others have pointed out that anatomical features of the fossil provide solid evidence that it was bipedal and therefore of hominid status. In April 2005, Brunet released a statement that analysis of the basal portion of the cranium suggested that Toumai may have been an upright biped. The most heavily scrutinized of the anatomical features is the foramen magnum. This is the large opening at the base of the cranium through which the spinal cord passes. Brunet stated that features of this opening pointed to upright posture that is similar to modern humans. One of these was the angle between the foramen magnum and the orbital plane. The orbital plane is the surface along the maxilla, or upper jaw, that lies perpendicular to the Frankfort plane at the orbitale. Among humans, the angle between the foramen magnum and the orbital plane is nearly perpendicular. In chimpanzees, this angle is more acutely angled, indicative of pronograde posture. According to Brunet, Toumai displays an angle closer to that of humans. Critics state

that the foramen magnum is positioned too far back on the base of the skull to have supported a head on an upright body. Since bipedalism is one of the noted features of the hominid lineage, proving Toumai's upright posture is of great importance to the ape-hominid debate. If Toumai is accepted as a hominid, then bipedalism and the human-chimp divergence occurred much earlier than once assumed.

The mixed features of this specimen remain somewhat enigmatic for both supporters and skeptics. The face is relatively flat, and a prominent brow ridge is present above the eyes. These characteristics are found in hominids dating after two million years ago but not the majority of the fossils found between four million and two million years ago. Hominids dated in this time period had more protruding faces and lacked brow ridges. These are also features that are not found among the Miocene apes. Also, while support for Toumai being bipedal is gaining strength, the brain case has apelike proportions of approximately 320–350 cubic centimeters. The unique mix of derived and primitive charac-

teristics not only raises questions but further suggests that the evolution of ape to man was anything but a straight progression.

If this specimen is a hominid, then it will change the previously accepted version of both when and how the hominid lineage evolved. If it is a Miocene ape, it can add information to the sparse pool of knowledge about the development of African apes. The possibility of this fossil representing a failed line of hominid-ape divergence can offer a great wealth of information about changes occurring in the Upper Miocene, another area of which little is known. Whether or not this ancient specimen is a hominid, an ape, or a failed by-product of diverging lineages, its importance to our understanding of evolution is immense.

■ Introduction: Increasing Diversity—Our Ancestors of the Pliocene, 5–1.8 Million Years Ago

If you had to divide the story of human evolution into two chapters, the first would be the evolution of bipedalism from a quadrupedal ancestor, and the second would be the evolution of brain size beyond the size of that of living chimpanzees. The latter chapter, the brainy episode in human evolution, began about 1.8 million years ago. Before that, the first chapter takes place mostly during the Pliocene epoch from 5 million to 1.8 million years ago.

Bipedalism may not have been the reason that the hominin lineage separated from that leading to chimpanzees, but regardless, once upright posture and locomotion became important, natural selection spent at least three million years tinkering with the hominin body to be increasingly better at it. The fossil record throughout the Pliocene documents this transition from

very primitive apelike bodies to much more derived bipedal ones, especially from the waist down. (Shorter forearms and mobile yet strong shoulders, good for throwing, did not evolve until the Pleistocene.)

By the time the Pliocene epoch begins, *Ardipithecus* is in full swing. This is a genus with two named species that lasted about 1.5 million years (from 5.8 million to 4.4 million years ago) in what is now Ethiopia. *Ardipithecus* is a contender for the earliest bipedal hominin because of the anatomy of the feet, but it will remain disputed until the much-awaited partial skeleton is revealed to the scientific community by discoverer Tim White and colleagues.

The next hominin through time during the Pliocene is the first australopith, *Australopithecus anamensis*, dating from about 4.2 million to

Skulls of various hominid species, with a modern chimpanzee and human for comparison, show their diverse features. There are no mandibles yet for Sahelanthropus. (Illustration by Jeff Dixon)

3.8 million years ago. Thanks to a well-preserved tibia (shinbone) and some other fragments, it is clear that this hominin walked upright on two legs. Trends in tooth and jaw size and shape suggest that there is an evolutionary ancestor-descendant relationship running from *Ardipithecus* to *Australopithecus anamensis* and then to the next hominin through time, which is *A. afarensis*.

A. afarensis, known best for the iconic partial skeleton nicknamed “Lucy,” lived in Ethiopia, Kenya, and Tanzania (and perhaps Chad) from approximately 4 million to 2.5 million years ago. By this time, bipedal adaptations have moved further throughout the body, with a well-preserved knee, hips, foot bones, and footprints pointing to dedicated bipedal locomotor behavior. However, this hominin, living halfway be-

tween the beginning (about six million years ago) and the end of the hominin story (modern *Homo sapiens*), still had some anatomy that could have been useful for climbing, like slightly long and curved fingers and toes. It also had a chimpanzee-sized brain (estimated from fossilized skull bones), and it did not leave any evidence that it used tools or that it ate animals to any significant degree. *A. afarensis* was essentially a bipedal chimpanzee.

At about three million years the hominin tree becomes diverse. This is about when fossils of *A. africanus*, which is a lot like *A. afarensis*, show up in South Africa, and subsequently, in both regions, a new separate kind of hominin appears. These are the robust australopiths, and they are more and more often designated as a separate genus, *Paranthropus* (a genus that is often labeled *Australopithecus* as well). With massive jaws, anchored to the cranium with meaty chewing muscles, and with enormous molars, *Paranthropus aethiopicus*, *P. boisei*, and *P. robustus* were adapted for chewing tough fibrous vegetation and for cracking and grinding hard nuts, seeds, and fruits. Based on the currently available evidence, everything else about their bodies, including the brain size, is australopith-like. *Paranthropus* seems to thrive long after australopiths are extinct and until one million years ago. For about one million years these small-bodied large-jawed vegetarians were living simultaneously with and in the same regions as newly evolved members of the genus *Homo*.

Some of the big questions for paleoanthropologists who work on the Pliocene fossil record are: (1) Which species gave rise to *Paranthropus*? (2) Which species is the ancestor to the genus *Homo*? (3) Which species is responsible for making the earliest stone tools on record, dated to 2.6 million years ago from Gona, Ethiopia? This last question is crucial to efforts at reconstructing the evolution of the human genus. It has been long assumed that only members of *Homo* manufactured stone tools, that is, modified stones into particular shapes with sharp edges that were useful for butchering animals or preparing vegetation. The earliest fossil *Homo* is dated to about 2.3 million years ago, which is a

good 300,000 years after the Gona tools were left behind.

Ardipithecus ramidus

Ardipithecus is a very early hominid who lived some 4.5 million years ago in the forests of eastern Africa. Fossils of *Ardipithecus ramidus* were found in 1992 and 1993 in Aramis, Ethiopia, by Tim White, Gen Suwa, and Berhane Asfaw and their team. The remains include several isolated teeth, a basal skull part, some arm bones from a single individual, part of a lower jaw of a child, and a heavily fragmented incomplete skeleton. The estimated age is 4.4 million years. *Ardipithecus ramidus* was described in 1994 by Tim White and colleagues as a new *Australopithecus* species, but a year later they gave it its own generic name, warranted by the lesser-derived morphology of the skeleton. At present, *Ardipithecus* is considered a sister-taxon of *Australopithecus*, which means that they share a common ancestor.

Ardipithecus is suggested as one of the oldest members of human lineage, though not a direct lineal ancestor. The oldest member is, at present, *Orrorin tugenensis* of six million years ago, described by Brigitte Sénut and colleagues in 2001, alternatively named *Praeanthropus*. *Orrorin* is, however, not accepted by all scientists as a hominid. The status of *Sabelanthropus tchadensis* of Chad, estimated age between

six million and seven million years ago, is even more debated, though most scientists agree that it is an ape and not a hominid. If these two genera are dismissed as ancestral hominids, the honor goes to *Ardipithecus*.

Although *Ardipithecus* has many apelike features, it has some derived features as well, which makes it transitional between apes and australopithecines. It was about as large as a chimpanzee, with a height of only 2.6 feet (80 centimeters) and its brain was approximately the same size as that of a chimpanzee. The arm shows a mixture of apelike and derived features. The teeth of *Ardipithecus* are even more apelike than those of the *Australopithecus afarensis*. The back teeth are narrower, the enamel layer on them is very thin, and the front teeth are large, although the canine teeth are not as large as in living apes. The diet of *Ardipithecus* was similar to that of the living great apes. But some dental features are more similar to the australopithecines, including low, blunt, and less-projecting canine teeth; the somewhat smaller anterior teeth; and the somewhat broader lower molar teeth.

Ardipithecus led mainly an arboreal life but may have walked upright, as suggested by the structure of its toes and the position of the foramen magnum, which is found close to the base of the skull.

Two species of *Ardipithecus* have been described to date: *A. ramidus* of 4.4 million years ago and *A. kadabba* of 5.2–5.8 million years ago, both from Ethiopia. The differential diagnosis, however, is based on one canine tooth only, which seems to be more apelike in *A. kadabba* than in *A. ramidus*. Not all scientists recognize *A. kadabba* as a species on its own.

Australopithecus anamensis

In 1994 Meave Leakey of the National Museums of Kenya led an expedition that unearthed a wealth of hominid fossils. The fossils were found in Kanapoi and Allia Bay near Kenya's Turkana Basin. Initially these were classified as belonging to the *Australopithecus afarensis*. However, upon further analysis marked differences led to reclassification of the fossil as *Australopithecus anamensis*. The name is derived from the word *anam*, meaning "lake" in the local Turkana language of the basin area. Among the fragments found were portions of a lower and upper jaw, part of a tibia, and various teeth. A portion of a humerus, found at Kanapoi by a Harvard expedition in 1965, has since been associated with this species. The Leakey find had a significant impact on establishing the identity of the hominid and shedding light on the nature of human evolution.

All *A. anamensis* sites are found near Lake Turkana. Associated animal fossils indicate that the region was once a combination of dry woodlands, gallery forests along rivers, and more open grasslands. Of these sites, Kanapoi and Allia bays have proven the most significant. This area is characterized by Pliocene sedimentary sequences. Studying these sequences has been one of the keys to dating the fossils found.

At Kanapoi the strata sequences have been dated at 4.17 million to 3.5 million years ago. Hominid remains from two different levels, lower and upper, have been found within this sequence. The lower level was deposited during a time when the majority of the area consisted of Lake Lonyumun, about 4.1 million years ago. Most of the fossils found in this layer are tooth or tooth fragments, which have assisted in creating a more vivid image of what the hominid's diet may have been. Postcranial elements have been located in the upper level of the sequence, roughly dated at about 4.1 million to 3.5 million years ago. In this layer fossils were unearthed in a small river channel below the Kanapoi Tuff, which is about 3.5 million years old. To date, some of the more significant elements found in this level are a distal humerus and a nearly complete tibia.

Allia Bay, adjacent to Kanapoi, has yielded many important fossils, including mandibular

fragments and isolated teeth. Elements found at Allia Bay were discovered both within and below Moiti Tuff, which is 3.9 million years old. These fossils were found near what archaeologists have determined to be an ancient river named the Proto-Omo.

Based on the fragmented fossils found, researchers were able to establish various characteristics of *A. anamensis*. These include an interesting mix of primitive and advanced features.

The cranial and dental elements are somewhat apelike as is common among australopithecines. The cranial capacity for *A. anamensis* is small, and the teeth are adapted for coarse foods. Also, the ear holes in this fossil are small and elliptically shaped, as is seen in apes. The dental characteristics of this specimen are also primitive and apelike. Tooth enamel thickness suggests a diet consisting of tougher foodstuffs such as robust vegetation. Inspection of the fossil's teeth revealed that the molars are large relative to the size of the body. Also, the molars were large in comparison to the incisors. These are both dental characteristics found in australopithecines. The overall dental features of *A. anamensis* are primitive and apelike.

In contrast with the primitive features of the cranial and dental elements, postcranial elements display more advanced hominid features. Analysis of the shape of the tibia revealed that *A. anamensis* was bipedal. For example, the thickness of the tibia's distal portion indicates an area adapted for high stress, as would be necessary for bipedal locomotion. Also, the proximal articular condyles, which connect with the femur to create the knee joint, are deeply concave, wide in the antero-posterior plane, and equal in size. These are all traits found in the tibias of modern humans. Oddly, the tibial features may share more with the genus *Homo* than with chronologically adjacent australopithecines, such as *A. afarensis*. Such mixed traits support the hypothesis that sister branches of *Homo* and *Australopithecus* coexisted during this time, thus buttressing the theory that evolution was anything but a simple linear progression.

The Footprints at Laetoli and the Significance of Walking Upright

Some 3.7 million to 3.6 million years ago, two adult hominids and a child accidentally left their footprints in the volcanic ash from the eruption of Mount Sadiman at Laetoli in northern Tanzania. Their trail is the first direct evidence that these ancient hominids walked upright on two feet. The series of 59 imprints, which run over a length of at least 91.8 feet (28 meters), was discovered in 1978 by Mary Leakey and Tim White. The lines run parallel and close to each other. The stride length was relatively short compared to those of modern humans. Based upon the stride length and the size of the individual footprints, the stature of the hominids is estimated at about 4 feet (1.2 meters) for the smaller adult and 4.5 feet (1.4 meters) for the larger adult. Fossils of *Australopithecus afarensis* were found nearby, and the tracks are attributed to this species.

There is no general consensus on the interpretation of the hominid footprints at Laetoli. The only accepted view is that they were made by an upright-walking hominid, be it chimplike or humanlike. This way of locomotion is called bipedal, opposite to quadrupedal (four-footed). The trail lacks any evidence of knuckle walking as is displayed by the great apes. The points of discussion focus mainly on what the imprints resemble most and who made them.

According to one view, defended by Mary Leakey, Tim White, Richard Tuttle, and Ian Tattersall, the footprints perfectly resemble those of modern humans, with short and straight toes. Based upon this, attribution of the trail to *Australopithecus* is either dismissed (Richard Tuttle) or accepted (Mary Leakey and others). According to another view, shared by Jack Stern, Randall Susman, and Ronald Clarke, the footprints are more like those of an upright-walking chimpanzee, with long curved toes and a diverging big toe. Stern, Susman, and Clarke hold that they were made by *Australopithecus*.

A trail of fossilized footprints found by Andrew Hill at Laetoli in present-day Tanzania in 1976. Some of the oldest hominid evidence found in Africa, these footprints show that these hominin ancestors were walking upright in East Africa 3.5 million years ago. (John Reader/Photo Researchers, Inc.)

The transition from quadrupedal locomotion to a fully bipedal locomotion has significant advantages. Several theories have been developed to explain its importance. They focus on either the importance of having hands and arms free or the advantages of the new way of walking itself. Free hands and arms open the way to carrying food, infants, and objects; the more systematic use of tools, including weapons; and throwing stones toward enemies and predators. All of these advantages increase the survival chances of the first upright-walking hominids. Walking upright is efficient because the energetic costs are lower per unit of distance. Walking upright is also advantageous from a strategic point of view because it affords a better overview during

traveling. An interesting yet poorly supported theory is that bipedalism evolved in the water. Wading through shallow waters or wetlands is easier while walking upright. The absence of a hairy coat would have further facilitated it.

Hominids are the only primates with efficient upright walking as the primary form of locomotion. Only in our own lineage was a striding gait, whereby weight is alternately placed on a single fully extended hind limb, developed to its full extent. This required drastic changes in the skeleton, especially in the foot, long leg bones, and pelvis. Grasping abilities of the foot are lost, because after the heel has touched the ground during walking, the toes are pushed off, especially the big toe. The knee can be extended fully to make long strides. The legs are placed more closely to each other to prevent the center of gravity from swinging from left to right at each step. The weight transfer from the body to the legs has to change to keep balance. All major structural changes are already seen in the australopithecines, but there is no agreement about to what degree. *Australopithecus* most likely was not bipedal in quite the same way that modern humans are.

The type of upright walking of the great apes with bent knees and hips is energetically inefficient. Our way, with straight knees and hips and long strides, is energetically efficient. The amount of energy spent on locomotion is thus considerably reduced. Trained apes as well as monkeys still exhibit the bent knee and hip type of upright walking. Anatomical constraints apparently block the development of a striding gait.

Since the discovery of our early ancestors, the question of how our obligate bipedalism arose is fiercely debated. The early theories of the 1920s and 1930s follow the idea of a gradual and straight-lined evolution. The start was supposed to be a gibbonlike climbing and brachiating (arm-swinging) stage. The next stage was perceived as a chimpanzee-like knuckle-walking stage, culminating in our striding-gait bipedalism. The discovery of many new fossils and a better knowledge of the locomotion of the great apes shaped the theories constantly.

In the late 1960s a new initial stage was launched, that of vertical clinging and leaping with orthograde back and extended knees and

hips, first formulated by John Napier and Alan Walker. A variant of this hypothesis is that of an orangutan-like vertical climbing. The knuckle-walking stage has been promoted as more pronounced since the 1970s (e.g., by Sherwood Washburn) and is evidenced by our close genetic ties to chimpanzees. Whether the wrist of *Australopithecus* was fit for knuckle-walking or not is still under debate. A new and interesting theory was proposed in the mid-1990s by John de Vos, who sees an evolutionary parallel in the elongation and straightening of the limbs in all plain-dwelling animals, such as ungulates. The result is increase in speed and energetic efficiency. Most likely, as long as hominid fossils are unearthed, the fire of this debate will be fed.

Australopithecus afarensis

Australopithecus afarensis lived in East Africa between 3.9 million and 2.7 million years ago. They walked upright but were also good climbers. This species had low foreheads with prominent eyebrows, flaring cheeks, and a protruding face. Their build was slender (gracile), with long arms and short legs like an ape. The average cranial capacity of 430 cubic centimeters is comparable to that of a chimpanzee. The teeth were more apelike than those of the later *Australopithecus* species, with large front teeth, pointed canines, and small back teeth. Males were some

4.9 feet (151 centimeters) tall and weighed about 99.2 pounds (45 kilograms), while females were about 3.4 feet (105 centimeters) tall and weighed around 66.1 pounds (30 kilograms). Males had larger canines too, and their skulls had a prominent sagittal crest.

Australopithecus afarensis lived in a region with significant tectonic activity, with many volcanic eruptions and earthquakes. The fossils are generally found along what were rivers or lakes at that time, and most likely these australopithecines roamed their banks. *Australopithecus afarensis* was primarily adapted to a lake and river margin grassland environment, such as savannas and open woodlands. Fossilized pollen tells us that the forests along the rivers consisted of juniper and olive trees. Their diet was not restricted to fruits, seeds, leaves, and roots from the woodlands but instead included also grasses and sedges and probably occasionally termites, bird eggs, and maybe meat as well. The landscape of Dikika in Ethiopia, where *Australopithecus afarensis* fossils were found, can be reconstructed based on the faunal remains. There were rivers or lakes with hippopotamids and crocodiles and woodlands with African buffalos but mainly open grasslands with abundant extinct relatives of the wildebeests, rhinocerotids, elephants, and impalas of today. The lifeways of *Australopithecus afarensis* itself can only be guessed at. Stone tools and other archaeological evidence were never found, and the fossil sites do not represent living floors.

The majority of *Australopithecus afarensis* fossils originate from Ethiopia (Hadar, Aramis, Dikika); other localities are in Kenya (Lake Turkana, possibly also Koobi Fora and Omo), Tanzania (Laetoli), and South Africa (Makapansgat). The most spectacular findings are doubtlessly an incomplete skeleton of an adult female (“Lucy”), a group of 13 individuals (“The First Family”), and a complete right knee joint (“Johanson’s Knee”), all from Hadar, and the skeleton of a three-year-old girl (“Selam”) from Dikika. The species *Australopithecus afarensis* was officially named and described in 1978 by Donald Johanson and Tim White, based upon the remains known at that time.

The first finding of *Australopithecus afarensis* was not that of the famous “Lucy” but rather

Skeletons of different hominins show their relative body sizes, bone thicknesses, and limb proportions. Bones of the hands and feet were omitted for simplicity and also because few were preserved with the *H. erectus* skeleton. (Illustration by Jeff Dixon)

was a complete right knee joint with some more fragments of both legs (AL 129-1) nicknamed “Johanson’s Knee.” It belongs to an adult individual and is almost a miniature of a modern human knee. Because of this close resemblance, the knee is seen as evidence for upright walking. A year later, Johanson and his team found “Lucy” (AL 288-1), also at Hadar. This skeleton belonged to an adult female of about 20 to 25 years of age, about 3.5 feet (107 centimeters) tall and weighing some 61.7 pounds (28 kilograms). Her pelvis, thigh, and shin bones provided further evidence for upright walking. The same year, a lower jaw (LH 4) was found by M. Mubuala at Laetoli in Tanzania. This jaw would figure as the type specimen for the species in its 1978 description.

A year later, in 1975, Johanson’s team discovered the remains of several individuals at Hadar. Mike Bush, a medical student at that time, found an upper jaw fragment with hominid teeth. That was the very start of the discovery of a large assembly of hominids, including young adults and children at Afar Locality 333. The group was nicknamed “The First Family” by Johanson. The individual sizes show a considerable range, and this started the discussion of whether the group represents one, two, or even three species. Johanson and others maintain that all remains belong to a single species and explain the large

THE IMPORTANCE OF HADAR—THE DISCOVERY OF “LUCY”

The badlands of Hadar in Ethiopia’s Afar region yielded an impressive amount of early hominid fossils. One of the most important findings is “Lucy” (named after a popular Beatles song). Lucy is a skeleton of a female *Australopithecus* in her early twenties and was found on November 24, 1974, by Donald Johanson, Maurice Taïeb, and Tom Gray. Four years after the discovery, “Lucy” was launched as *Australopithecus afarensis*. At that time, “Lucy” and her kind were believed to be the common ancestors of all later hominids, including modern humans.

At the time, the skeleton was the first discovered skeleton of a fossil hominid. Not all parts have been preserved; completely missing are major parts of the skull, hands and feet, the shoulders, most vertebrae, and ribs.

The volcanic ash layers of Hadar can be dated, which provides an age framework for the fossils of *Australopithecus* that are found in the sediment layers sandwiched by the ash layers. This precise framework makes Hadar very important for early hominid evolution. Available dates of ash layers are 3.4 million years, 3.22 million years, 3.18 million years, and 2.95 million years.

—Alexandra van der Geer

size differences as due to the fact that males were much larger and stronger than females. Another hypothesis holds that the larger specimens belong to an early *Homo*. Actually, Johanson himself initially considered “The First Family” to be *Homo* in 1976; two years later, he and Tim White included the material into their description of *Australopithecus afarensis*.

In 1978, Mary Leakey and Tim White recognized a trail of hominid footprints at Laetoli in Tanzania, indicated to them by Paul Abell. The estimated age of the Laetoli footprints is 3.7 million–3.6 million years, based upon fossil findings nearby. The trail was made by three hominids: two adults and one child. There is disagreement about the nature of the footprints: humanlike or apelike. There is also disagreement about the

maker of the footprints: *Australopithecus* or early *Homo*. No hominid species other than *Australopithecus afarensis* is known from that region and that time, which favors the attribution of the footprints to this species.

The most complete *Australopithecus afarensis* skull to date was discovered in 1991 by Bill Kimbel and Yoel Rak at Hadar. The skull (AL 444-2) belonged to a large adult male. The brain size is 540–550 cubic centimeters. The skull is significantly larger than the smaller skulls of the same species, which fits the earlier observation that males and females indeed differed significantly from each other in size. This makes it more likely that “The First Family” indeed contains members of only one sexually highly dimorphic species.

In 2000 a skeleton and skull (DIK-1/1) of a three-year-old girl was discovered at Dikika in Ethiopia by Zeresenay Alemseged and team. The so-called Lucy's Baby is officially named "Selam," meaning "peace" in the Ethiopian language. With her estimated age of 3.3 million years, she is placed some 120,000 years before Lucy, which makes it impossible that "Selam" was Lucy's child. The practically complete skeleton preserves elements that were not recovered thus far. Scientists expect that this skeleton will shed new light on the anatomy and way of walking of *Australopithecus afarensis*.

Australopithecus afarensis, like the African apes of today, shared the upright (orthograde) posture of modern humans. The way of walking of *Australopithecus afarensis*, however, is considerably debated. The opinions range from almost exclusively bipedal to greatly arboreal. The reason for disagreement lies in its intermediate anatomy, with a mosaic of apelike and humanlike features. Apelike features are the long and curved fingers for grasping branches, a wrist-locking mechanism in the hand to enable knuckle walking, an upward tilted shoulder joint to use the arm above the head, relatively long arms for suspension, and a bony labyrinth of the inner ear that is not conducive to upright walking. Modern humanlike features, on the other hand, are the short and wide iliac blades of the pelvis, a wide sacrum that lies directly behind the hip joint, prominent attachment areas for the knee extensor muscles, an inward-orientated thigh bone resulting in a varus-knee, adducted big toes, and a derived ankle joint. The skeletal features that are used to explain its upright walking can also be explained as associated with vertical climbing. Most views today hold that the species walked upright and also climbed trees. A minority maintains that when on the ground, they practiced both upright walking and knuckle walking.

The discovery of a small-brained hominin with a primitive prognathic face that walked upright stirred the scientific world at first. Human evolution was supposed to first show an increase in brain size and only after that a shift to an upright posture and walking. The Taung Child (*Australopithecus africanus*) had already stirred the scientific establishment, but with the discovery

of *Australopithecus afarensis* in the 1970s, the earlier view had proven wrong. The current view is that first a shift in posture and locomotion took place and second an increase in brain size. The most commonly held view nowadays is that this species gave rise to the East African robust australopithecines, or possibly to all robust forms, and not to *Homo*. This honor goes at present to *Australopithecus africanus*.

Australopithecus africanus

Australopithecus africanus lived in southern Africa between 2.8 million and 2.4 million years ago. With its relatively short legs, long arms, and a chimpanzee-sized brain, this hominid was more like an ape than a human. The skeleton shows adaptations for upright walking as well as for climbing. The chewing teeth are large and have a thick enamel layer. Sexual dimorphism, or the size difference between males and females, is marked as in all earlier hominids. Males were about 54.3 inches (138 centimeters) tall and weighed some 90.3 pounds (41 kilograms), against the 45.2 inches (115 centimeters) and 66 pounds (30 kilograms) of the females. The brain capacity was about 440–625 cubic centimeters, a little larger than that of *Australopithecus afarensis*. They ate fruits and leaves but also large quantities of grasses and sedges or animals that ate these plants. Their habitat was open, such as woodlands and grasslands. *Australopithecus africanus* is considered close to the ancestry of the *Homo* lineage.

The name *Australopithecus* was coined by the Australian anatomist Raymond Dart (1893–1988) in February 1925. He based his new species *australopithecus africanus*, meaning Southern Ape of Africa, on the skull of a child.

➤ SWARTKRANS AND THE TAUNG CHILD

In 1924, the first evidence of ancestral humans from Africa was unearthed. Until then, our ancestors were believed to come from Asia or Europe, not Africa. Raymond Dart found the skull of a young child among other fossils from a quarry near Taung in South Africa. He gave his “Taung Child” the scientific name of *Australopithecus africanus*, literally Southern Ape from Africa. The genus name *Australopithecus* is now the common label for a larger group of pre-*Homo* hominids.

Swartkrans cave, discovered in 1948 by Robert Broom, is the most productive hominid site in South Africa. Between the late 1960s and early 1980s, remains of 130 individual hominids were recovered here. The bones are a mixture and belong to a number of species, including *Australopithecus robustus* and *Homo erectus*. Many *Australopithecus* bones bear chewing marks, and one skull shows punctures made by the canine teeth of a large cat. Apart from the human bones, other animal bones were found that show butchery marks originating from stone tools. A number of animal bones from the one million-year-old level are burned, indicating the use of fire by early *Homo*. Swartkrans shows that late *Australopithecus* and early *Homo* possibly lived contemporaneously in the same region.

—Alexandra van der Geer

In boxes with fossils from a limestone quarry at Taung, South Africa, Dart had discovered a natural endocast of a braincase in 1924. He immediately realized that it belonged to a higher primate. This petrified brain imprint fitted to skull parts from another limestone block. Dart spent months removing the hard matrix around the fossils and with good result. His specimen turned out to be a child of about three to four years of age with a full set of milk teeth and its permanent molars just starting to erupt. Dart proudly considered it his Taung baby.

Dart realized that *Australopithecus africanus* could not be an ape, because the South African climate had been relatively dry for the last one million years. Features of the skull and teeth were more akin to humans than to apes, but the brain was too small. The estimated brain size if it had grown to adulthood is 440 cubic centime-

ters, which is somewhere in between that of the average gorilla and the orangutan. However, compared to a comparable-sized ape, the bonobo, the Taung child would have had a brain one-quarter larger as an adult. Dart postulated that *Australopithecus africanus* was a missing link between humans and apes, pointing out the hominid-like features of his fossil.

The established scientific community refused to accept Dart's view of a species intermediate between apes and humans. The commonly held view at that time was that human ancestors were to be found either in Asia or elsewhere in Africa. Furthermore, the missing link was expected to combine an enlarged brain with an apelike jaw. A small-brained ancestor was simply unacceptable. In addition, a juvenile skull was not a very trustworthy basis for a missing link.

Another unlucky coincidence was that at the very time Dart promoted his ideas, fossils of a primitive kind of *Homo* (“Peking Man”) had been discovered in China. Before that, similar fossils had been found in Indonesia in the 1890s and Europe from where the famous Neanderthals came. No one at that time considered Africa a possible birthplace for ancestral humans, despite Charles Darwin's observation on the similarity between the living species and the fossil species in the same region. The disappointment was large enough for Dart to cease working with the fossils for almost 20 years. By the early 1950s, based upon discoveries of rich fossiliferous sites in South Africa by Robert Broom (Sterkfontein 1936, Kromdraai 1938, Swartkrans 1948) and Dart himself at Makapansgat in 1947, the scientific community finally accepted the view of *Australopithecus* as early hominids, not just some kind of aberrant apes.

The second *Australopithecus africanus* fossil that was found belonged to an adult individual. In it is a heavily fragmented skull (TM 1512) with brain endocast. The endocast was discovered on August 17, 1936, by quarry foreman G. W. Barlow in the Sterkfontein quarry. He showed it to Robert Broom, who subsequently found skull fragments in the rubbish. Originally, he described the remains as *Plesianthropus transvaalensis*. On April 18, 1947, he found a very well-preserved adult skull in the same quarry. The skull, nicknamed Mrs. Ples (STS 5), is now

thought to be male (“Mr. Ples”). A nearly complete backbone, a pelvis, a part of a thigh bone, and some rib fragments (STS 14) from the same cave, found in the same year, seem to belong to the skull. This skeleton provides so far the only available information about body proportions of this australopithecine.

Australopithecus africanus was initially considered a forerunner of one or all of the later robust australopithecines. The back teeth are broader and have thicker enamel than those of *Australopithecus afarensis*, traits that are also present in the robust forms. The current view, however, is that *Australopithecus africanus* evolved into the genus *Homo*, more precisely into *Homo habilis* or *Homo rudolfensis*, dependent on the theory followed. This view is based upon its rounder skull and larger brain. The teeth and face seem less primitive, too. *Australopithecus afarensis* (“Lucy”) and the robust australopithecines (*Paranthropus*) are now seen as side branches without descendants.

A matter that complicates the possible ancestry of *Homo* is the unexpected apish limb proportions of a *Homo habilis* skeleton (OH 62) found in 1986 in Olduvai. The ratio of upper arm length to upper limb length of OH 62 is more apish than that of *Australopithecus afarensis*. It seems thus that some early members of *Homo* had apelike body proportions. Similar proportions are seen in *Australopithecus africanus*, which made it a good candidate for direct ancestry. An interesting new view was recently proposed by Bernard Wood, following an earlier remark by John de Vos in the mid-1990s. They suggest that *Homo habilis* and *Homo rudolfensis* are in actual fact australopithecines. In that case, the problem with OH 62 is nonexistent, and the ancestry of early *Homo* (*Homo ergaster*) is again open to discussion. The exact relation of *Australopithecus africanus* to the earliest *Homo* is, again, still under debate.

The Robust Australopithecines—*aethiopicus*, *robustus*, and *boisei*

Three robust australopithecine species—*aethiopicus*, *robustus*, and *boisei*—stand somewhat apart from the common lineage of gracile australopithecines. These species have a very heavy build despite their small size, relatively long arms, prominent crests on their skulls, very thick jaws, and long, broad, and flat faces. The known robust species are, from geologically old to young, *Australopithecus aethiopicus* (2.5 million years ago) from eastern Africa, *A. robustus* (2.0–1.0 million years ago) from southern Africa, and *A. boisei* (1.8–1.4 million years ago) from eastern Africa. The most robust species of the three is *robustus*. The dentition of the robust australopithecines is suitable for a highly abrasive diet. They had a strictly vegetarian diet in contrast to the gracile australopithecines, who occasionally ate meat. Like all australopithecines, they were small, reaching a height of only 3.6–3.7 feet (1.1–1.4 meters), with a small-sized brain of about 410–545 cubic centimeters. The robust australopithecines were adapted to mixed grassland and woodland environments.

Since the discovery of the Taung child (*Australopithecus africanus*) by Robert Dart in 1924 in Transvaal, hundreds of fossil fragments of similar hominids were found throughout South Africa. They were in the first instance divided into two groups, the robust and the gracile types. The first named robust species is *Australopithecus robustus*. Its fossils come mainly from Swartkrans, Drimolen, and Kromdraai caves, all in South Africa.

Their history starts in 1938, when Robert Broom discovered skull fragments, including five teeth and some skeletal fragments (TM 1517), at Kromdraai cave in South Africa. The very first remains were discovered by Gert Terblanche, a schoolboy, earlier that year. Broom learned from Gert and his family where the fossil teeth came from and collected several specimens himself. Based upon the intermediate features between humans and apes, the remains became known as the “Kromdraai Ape-Man.” Originally, he officially named it *Paranthropus robustus* in 1938, but later the robust types were renamed to *Australopithecus*.

► OLDUVAI GORGE

Located in northern Tanzania, the Olduvai Gorge is known for two significant discoveries regarding human evolution. Olduvai was made famous by anthropologists Louis and Mary Leakey in the late 1930s. However, the region's political turmoil prompted their premature departure; although their initial findings were of the earliest known Paleolithic tools, upon their return in 1959 the Leakeys discovered remains of some of the earliest known hominids.

The tools that the Leakeys discovered date to over two million years in age. In addition to hand axes, the Leakeys discovered Oldowan tools, which are considered the oldest known stone tools. The name “Oldowan” was first used by Louis Leakey to refer to the lowest geological stratum in the find spot of Olduvai Gorge in Tanzania.

In 1960 Mary and her son Jonathan discovered the remains of what they named *Homo habilis*, and in 1972 son Richard Leakey discovered the “Turkana Boy,” another *Homo habilis* specimen. Both date to about two million years old. *Homo habilis* was a controversial find but is now accepted as the first member of the genus *Homo*. The term *habilis* was applicable because of their use and creation of tools. Although there is still controversy about the Leakeys’ findings in relation to human evolution, many agree that the Olduvai Gorge is significant for learning about early life and development.

—Shamika Ann Mitchell

Olduvai Gorge in northern Tanzania, where remains of some of the earliest known hominids were discovered. (William Warby)

Later, a skull (SK 48), probably of an adult female, was discovered at the same Swartkrans cave in 1950. Of the same geological age is an almost complete skull and lower jaw (DNH 7) of another female, nicknamed “Eurydice.” It is one of the most complete hominid skulls found to date. The remains were discovered in 1994 at the Drimolen cave in South Africa. Nearby, a lower jaw (DNH 8) of a male of the same species was found. Not surprisingly, he became known as “Orpheus.”

The second discovered robust species is *Australopithecus boisei*. A male skull (OH 5) was discovered in July 1959 at Olduvai Gorge, Tanzania, by Mary Leakey. The skull is almost complete and was nicknamed the “Nutcracker Man” because of its robust dentition. Originally, Mary

and Louis Leakey described it as *Zinjanthropus boisei*, but they later referred to the species as being of the genus *Australopithecus*.

More *Australopithecus boisei* fossils were found at Lake Turkana, Kenya, including an intact skull (KNM-ER 406) from the eastern side of the lake. Ten years later, a complete skull (KNM-ER 406), but without teeth, was found by Richard Leakey near Lake Turkana in Kenya. A year later, he found another skull (KNM-ER 732) in the neighborhood. The skull is similar to that of the “Nutcracker Man” (OH 5) but is smaller and lacks the prominent sagittal crest at the top of the skull. Based upon its smaller size and less massive look, most scientists believe this find to be a female’s skull. A geologically much younger specimen was discovered in 1993 by A. Amzaye

at Konso in Ethiopia. It is a partial skull with lower jaw (KGA 10-525), which differs in some anatomical aspects from the geologically older specimens. Dated to 1.4 million years ago, it is the last robust specimen from eastern Africa.

The most recently discovered robust australopithecine is *Australopithecus aethiopicus*. In 1985, Alan Walker found an almost complete skull (KNM-WT 17000) at the west side of Lake Turkana in Tanzania. The skull is known as the “Black Skull” because of its black color, which is caused by manganese in the soil in which it was deposited. With its estimated age of 2.5 million years, the skull is geologically the oldest robust australopithecine. The brain size of about 410 cubic centimeters is remarkably small, and the skull shows primitive as well as derived traits. The face is very similar to that of *Australopithecus boisei* from the same area, but the rest of the skull is more similar to that of *Australopithecus afarensis*. Originally, Walker and team assigned the “Black Skull” to the geologically younger *Australopithecus boisei*, but later it was honored with a species name of its own, *Australopithecus aethiopicus*, based on significant differences with the other species.

Typical for all robust species are the very large molar teeth and large molarlike premolar teeth combined with small front teeth and canines. The increasing grinding capacity of this dentition fits to the very thick jaws. The massive jaws, well-developed masticatory muscles, and large grinding surface of the molar teeth are specializations to a diet consisting of tough and fibrous plant materials. The most obvious difference between gracile and robust forms is that robust forms have

huge back teeth and small front teeth, whereas the gracile forms have larger front teeth compared to the size of their back teeth.

The ancestor of the robust species is not known. Both *Australopithecus africanus* and the more robust types of *A. afarensis* are suggested, but sufficient evidence is missing. The robust species are not considered ancestral to modern humans but instead constitute a side branch without known descendants. They became extinct around 1 million years ago in South Africa and by 1.4 million years ago in East Africa.

An increasing number of scientists are of the opinion that the three robust species differ too much from the gracile species such that a different genus name is warranted: *Paranthropus*. The genus name was already suggested by 1938 by Robert Bloom for the fossils from Kromdraai Cave but was dismissed later. At present, the earlier view seems to be reestablished.

■ Introduction: The Appearance of the Genus *Homo* at Two Million Years Ago

The first members of our genus—*Homo*—appeared in eastern and southern Africa around two million years ago. Various described as *Homo habilis*, *Homo ergaster*, and *Homo sapiens* (known also as *Kenyapithecus rudolfensis*), one of them—most likely *Homo*

ergaster—evolved into later forms of *Homo*, including our own species, *Homo sapiens*.

What makes these species part of our genus and not that of their contemporaries, which include *Australopithecus robustus* and *Australopithecus africanus*? A number of physical

HOMINID FOSSILS FOUND THROUGHOUT THE WORLD

features are important: larger cranial capacity, reduced size of canine teeth when compared to the australopithecines, hands with opposable thumbs, and more human-like body proportions. Although the australopithecines made stone tools generally associated with the Olduvan industry, *Homo habilis* made more complex, stone tools, suggesting an increasing reliance upon cultural practices to manipulate the environment and obtain food.

Although it is difficult to define with certainty the diet of these early members of our genus, it has been hypothesized that their diet had a much larger proportion of meat and fat than did either their ancestors or contemporaries. The presence of animal bones with cut marks at sites thought to have been occupied by our ancestors supports this inference, at least indirectly. It is not known at present if our ancestors hunted game or scavenged meat from animals killed by other predators.

However, given that many of our closest primate relatives hunt occasionally, it is likely that our ancestors at this time did as well.

Such relatively simple technologies and inferred cultural practices became more complex around 1.5 million years ago. Acheulian stone tool technology, with its characteristic hand ax forms, became more common, and our genus spread across much of eastern and southern Africa. This in turn set the stage for the appearance of *Homo erectus*, the first of our genus to leave Africa and migrate into much of South and Southeast Asia.

African Climate at Two Million Years Ago

The African continent contains a lengthy and dynamic history of environmental and geological change, often in spatial association with abundant evidence of human evolution. At the same time, many geographic zones such as the Serengeti Plains and the Sahara have changed little since their ecological development millions of years ago. The primary evidence for climatic change comes from the well-studied Pliocene-Pleistocene paleoanthropological sites that have yielded stone tools, hominin fossils, and vertebrate and invertebrate fossil material. This data predominantly comes from the East African Rift Valley and is supplemented by other environmental markers such as vertebrate faunal assemblages, pollen and phytoliths, sedimentary isotopic levels, deep-sea cores off of various African coasts, cave deposits, and numerous sedimentary sources throughout the continent. One of the most significant periods in human evolution was approximately two million years ago in East and South Africa, marking the time immediately before the evolution of *Homo erectus* and also a time when a member of the genus *Homo* migrated from Africa into Eurasia for the first time. Most importantly, this was the point when the Pliocene period, which began at about 5 million years ago, was about to end and the Pleistocene epoch was about to commence (ca. 1.8 million years ago, or the Plio-Pleistocene boundary).

About two million years ago East Africa and other regions in the continent witnessed radical changes in temperature, vegetation, fauna, topography, and drainage, all directly or indirectly linked with each other. The climate had already begun to become periodically cooler and drier by about 2.8 million years ago, and this trend continued in Africa and globally until the end of the Pliocene or approximately 1.8 million years ago. These oscillating cycles were a direct outcome of the expansion of high-latitude ice sheets that also led to stronger winds and an increasing but gradual transformation of some rain forest or woodland areas (i.e., closed canopy) into grasslands or open savanna environments. Grassland environments also played a major role in early

human evolution and ecological adaptations and dispersals into other areas. The expansion of grasslands is reflected in the phytolith evidence from stratified marine records correlated with the cooler intervals. This is further supported through stable isotopic analyses of pedogenic carbonates from well-preserved terrestrial sequences in the Olduvai and Turkana basins. In West Africa the temperature had dropped 3.5 to 10 degrees Fahrenheit (2 to 6 degrees Celsius) and in East Africa it had dropped 3.5 to 7 degrees Fahrenheit (2 to 4 degrees Celsius). Arid environments dominated the African continent (including present-day subtropical West Africa), in contrast to the humid phases prior to 2.5 million years and after 1.9 million years ago. Prior to 2.8 million years ago African climatic periodicity was at 23,000 to 19,000 intervals; between 2.8 million and 1.0 million years ago this variance increased up to a periodicity of about 41,000 as reflected in the eolian cycles detected in the marine record. This was a direct influence of remote forcing by cold glacial North Atlantic sea-surface temperatures. Overall, African climates were equally governed by intermittent volcanic and tectonic activity and the intensification of seasonal monsoon regimes.

Homo habilis—One Species or Two?

Homo habilis fossils were first identified as such by Louis Leakey in the early 1960s. The 1.9 million-1.8 million-year-old assemblage from Olduvai Gorge included upper and lower jaw fragments, skull pieces, and leg, hand, and foot bones. The teeth in the upper and lower jaws were more similar to those of humans than to

Discovered in the early 1970s at contemporaneous locations at Koobi Fora, Kenya, these skulls (left: KNM-ER 1813, right: KNM-ER 1470) typify the diversity of shape in early *Homo*. (The Natural History Museum, London/The Image Works)

the australopithecines, since the teeth were larger in the front and smaller at the back. The skull pieces lacked the bony crests typical for the australopithecines, were thinner, and reflected a larger brained hominid. Although not fully accepted at that time, most scholars now recognize these and similar fossils as belonging to early *Homo*. The contemporary 2 million–1.6 million-year-old fossil skull KNM-ER 1470, discovered at Koobi Fora by Richard Leakey several years later, was also classified as *Homo habilis*, though it revealed several cranial differences. The skull was much larger, and its jaws had australopithecine sized teeth. As more hominid fossils were collected, including KNM-ER 1813 from Koobi Fora, it became clear that two contemporaneous species lived in Africa at that time: *Homo habilis* and *Homo rudolfensis*. Based on the dates assigned to the fossil specimens, *Homo rudolfensis* is the oldest known species of *Homo*, perhaps joined by *Homo habilis* around two million years ago. *Homo habilis* fossils, such as KNM-ER 1813, 1805, 1501, and 1502 from East Turkana and five from Olduvai Gorge (OH 7, 13, 16, 24, and 62), are smaller brained, with an average endocranial capacity of about 630 cubic centimeters (cc). Their teeth are smaller and closer in size to later hominids. KNM-ER 1470, 1590, 3732, 1801, and 1802 and other *Homo rudolfensis* specimens, on the other hand, have larger cranial capacities, aver-

aging 750 cc, and larger teeth that are similar to those of the australopithecines. These fossils have long faces, are broad across the eye sockets, and are flattened below the nose, when compared to the short-faced *Homo habilis* skulls, which have a narrow space between the orbits and are more prognathic—that is, a forward-thrusting face—below the nose.

The postcranial elements also reveal differences between the two species. The arms of *Homo habilis* are long, which is a characteristic of the australopithecines, as are the curved finger bones. The early *Homo* species was relatively small in general, as was assessed by a group of 1.8 million-year-old fossils discovered at Olduvai Gorge in 1986. The teeth, fragments from the right arm, skull, and both legs are collectively known as OH 62 and belong to a single female individual. She was small, only 3.6 feet (109.73 centimeters) tall, just as *Australopithecus afarensis* was 1 million years earlier. Her long arms compared to her legs suggest that the tree-climbing ability of the australopithecines was retained. Alternatively, several large *Homo rudolfensis* femurs (upper leg bones) suggest a more humanlike skeleton, and its larger overall size distinguishes it from the australopithecines.

Dividing the fossil assemblage into two separate early *Homo* species is challenging, however. The total number of specimens is very small even before grouping them, and many of the bones lack species-specific attributes. Moreover, there are only eight skulls or partial skulls on which cranial capacity can be calculated. In fact, some scholars suggest that the fossil differences may reflect sexual dimorphism rather than two distinct species, whereby the larger robust specimens belong to the males and the smaller gracile (graceful, slender) pieces are from females.

Assuming that the fossil assemblage represents two separate species, the relationships between them, the earlier australopithecines, and the later *Homo ergaster* fossils remain unclear. *Homo habilis* fossils seem less humanlike than *Homo rudolfensis* specimens, but the large teeth and robust jaws of the latter species are also australopithecine-like. Which of these species, if either, is the ancestor to modern humans remains a matter of dispute.

—Shawn Bubel

THE HAND OF *HABILIS*

The name *Homo habilis*, popularly nicknamed “handy man,” was given in 1964 to an early human ancestor who was believed to be the producer of the stone flakes found at Olduvai, Tanzania. The shape of the hand was considered closer to that of *Homo* than to that of *Australopithecus* and apt for deliberately making tools. The type specimen is OH 7 from Olduvai, the fossil remains of a 12-year-old boy dated to about 1.75 million years ago. Only a lower jaw complete with teeth, an isolated upper cheek tooth, skull fragments, and about 20 fragments of his left hand were preserved. The hand bones show anatomical features indicating an ability to manipulate objects with precision. One of these features is a fully opposable thumb. However, fine precision grip, as is typical for modern humans, had not yet evolved because the wrist bones of OH 7 most resemble those of the African great apes. The tools ascribed to *Homo habilis*, stone

flakes and crude chopping tools, are very primitive, known as the Olduvian industry. They were used in scavenging, scraping meat from carrion, and not for sophisticated hunting as was originally believed. The somewhat more advanced hand of *Homo habilis* likely gave this species an advantage over the more primitive australopithecines in a changing environment.

Introduction: Out of Africa—*Homo ergaster* and *Homo erectus*

The first hominins or humans found outside of Africa belong to the species *Homo ergaster* and/or *Homo erectus*. These forms are often distinguished on geographic location or on anatomical features. While they are similar in their postcranial bones, the skull differs significantly. Asian *Homo erectus* fossils have an angular skull with a ridge extending from the metopic suture (in the center of the forehead) up to the sagittal suture (on the top of the skull). Combined with flattened parietal bones (the “walls” of the skull), this gives the

skull a gabled appearance. Some African fossils of similar age have a rounder skull, more like the later species *Homo heidelbergensis* (and modern *Homo sapiens*). But these members of *Homo ergaster* share a similar cranial volume (ranging from 750 to 1225 cubic centimeters) with the Asian *Homo erectus*. While the oldest members of this species date to around 1.8 million years ago in Africa, there are a number of African specimens that are less than 1 million years old (for example, Olduvai Hominid 9 and “Daka” from the Middle Awash in Ethiopia).

These younger ones look more like classic Asian *Homo erectus* skulls. The easiest explanation is that they all belong to a single variable species, *Homo erectus*.

The oldest members of this species come from a number of localities in East Africa. The most complete is the Nariokotome skeleton from the west side of Lake Turkana in northern Kenya. Dated to around 1.6 million years ago, it is composed of most of the body of a teenage individual. What was surprising is the stature; this individual would have been around 6.5 feet (2 meters) tall as an adult. Skulls of similar form come from the east side of Lake Turkana as well as from Olduvai Gorge. In North Africa, the same hominins are present at a number of sites in Morocco and at Ternifine (or Tighenif) in Algeria. In most locations, they are associated with Acheulean artifacts or with core and flake tool assemblages.

The first dispersal of humans out of Africa must have occurred by 1.7 million years ago. That is because of their presence at the site of Dmanisi in Georgia (in the Caucasus). Over the last two decades, a number of skulls, mandibles, and most recently postcranial bones representing most of the body have been recovered from early Pleistocene deposits under a medieval castle at Dmanisi. They are associated with pebble tools and flakes as well as with fossil animal bones.

The first place that *Homo erectus* was discovered was on the island of Java in Indonesia. In the 1890s Eugene Dubois, a medical doctor from the Netherlands, recovered a number of fossil animal bones and some human remains from the site of Trinil on the Solo River. The initial finds were a small skull cap and a modern-looking femur. It was the upright posture of the femur that led Dubois to name these specimens *Pithecanthropus erectus*, later changed to *Homo erectus*. The exact age of these fossils is not clear. Later on, others were found at different localities along the Solo River. While they are likely to be early Pleistocene, their exact age is uncertain.

Similar fossils began being found in China starting in the 1920s. The most important Chinese site has been Zhoukoudian, or the “Peking Man” site, on the edge of modern Beijing. (Note that the fossils are still referred to as “Peking Man” although the name for the capital of China became

Beijing, using the Pinyin orthography.) As is the case at most Asian *Homo erectus* sites, the stone artifacts that these people made were cores and flakes, not the bifaces of Acheulean people. The oldest deposits at Zhoukoudian have been recently redated to around 700,000 years old.

So when did the first humans leave Africa? It must be by 1.7 million years ago in order to get their descendants to Dmanisi and beyond. Slightly before this time, humans had achieved a modern body form. Various researchers have suggested that key changes in social behavior and diet have occurred by this time. These would involve living in larger social groups, increasing mobility over a larger territory or range, and the reliance on meat in the diet. As brain size increased, babies would have to have been born more and more immature. Therefore, there needed to be more parental investment with offspring. While some of these innovations are thought to be associated with the appearance of Acheulean technology, it is clear that early humans left Africa well before the Acheulean was invented.

Africa—*Homo ergaster*

Homo ergaster is a species defined by Groves and Mazak using a single mandible from Koobi Fora, the east side of Lake Turkana, Kenya (KNMER 992). It was described as being more like anatomically modern *Homo sapiens* than its contemporary, *Homo erectus* in Java and China, and it could have been the direct ancestor of *Homo sapiens* in Africa. If this is so, there would have been two parallel lines in later human evolution: one in Africa and one in East Asia. For other researchers, *Homo ergaster* is just a variety of *Homo erectus*. *Homo ergaster* ranges in time from 1.8 million to around 500,000 years ago, while the Asian species can continue up to around 250,000 years ago (at Zhoukoudian in China, for example). Regardless of this debate, *Homo ergaster*/*Homo erectus* is the earliest

LOCATIONS OF AFRICAN SITES WHICH HAVE YIELDED FOSSIL REMAINS OF *HOMO ERGASTER*

hominin with a body size within the modern range and the first found outside of the continent of Africa. For paleoanthropologist Bernard Wood, it is even the oldest species within the genus *Homo*. The tools produced by *Homo ergaster* were either pebble tools or Acheulean bifaces. Neither was a great leap forward in cultural evolution. In fact, Acheulean tools look remarkably similar for thousands of years.

Classic Asian *Homo erectus* skulls are angular, with a brain case ranging from 775 to 1,225 cubic centimeters. The frontal bone has a keel or prominent ridge along the metopic suture. It extends into a midsagittal keel between the parietal

bones. Early *Homo ergaster* specimens in Africa, on the other hand, have rounder skulls. While these are similar in size to Asian *Homo erectus*, they are shaped like those of *Homo sapiens*. Asian forms have quite thick cranial and postcranial bones. These features are variably present in Africa. But both share facial features such as a continuous supraorbital torus, a large projecting face and teeth, and no chin in the mandible. The postcrania are similar in form and size to those of modern humans. But the femur or thigh bone is platymetric or flattened in cross-section.

In Africa, a number of sites contain fossils of *Homo ergaster*. Most of these are single finds,

associated with pebble tools or Acheulean bifaces. In Morocco, the site of Thomas Quarry 1 produced a mandible and cranial vault (top of the skull), while nearby Sidi Abderrahman produced another mandible and an isolated tooth. At Salé, there is a partial vault and face. At Tighenif (formerly Ternifine), in Algeria, three mandibles, one parietal bone, and some teeth were recovered along with Acheulean tools. A single skull that is about one million years old comes from Buia in Eritrea; it is described as having a mixture of traits of *Homo ergaster* and *Homo heidelbergensis*. From the site of Dakaniyo or Daka in the Bouri Formation of the Middle Awash, there was a skull, three femora, and a proximal tibia fragment, also about one million years old. At the Acheulean site of Konso-Gardula, there is a mandible fragment. The most spectacular find has come from Nariokotome, West Turkana, in northern Kenya. Here researchers recovered an almost complete skeleton of a teenager. About 1.6 million years old, it was about 5.25 feet (160 centimeters) tall with skinny tropical body proportions. On the east side of Lake Turkana, in addition to the KNM-ER 992 mandible, two skulls were recovered (KNM-ER 3373 and 3883). These are around 1.8 million to 1.7 million years old and show the rounded skull with thin cranial bones, which is definitive of *Homo ergaster*. Farther south in the Kapthurin Formation of Lake Baringo, researchers have recovered some hominin mandibles and postcrania. In southern Kenya, the Acheulean site of Olorgesailie has yielded a single frontal bone. At Olduvai Gorge in northern Tanzania, a number of *Homo ergaster* specimens have been recovered over the years, including the OH 9 skull, which dates to about 1.2 million years ago. In South Africa, the early site of Swartkrans has produced a mandible that is assigned to either *Homo habilis* or *Homo ergaster*.

Homo ergaster/Homo erectus is the first hominin who ventured out of Africa into Asia, sometime between 1.8 million and 1.7 million years ago. The focus of current research on this species is on this Out of Africa 1 dispersal. What was different about *Homo ergaster* that enabled some of them to spread out of Africa? Was their adaptation significantly different from

that of earlier African hominins? What was different about this species that enabled some of them to widen their range? Their bigger body and brain size and reduced gut size (relative to other living primates) may offer a clue. Aiello and Wheeler created the expensive tissue hypothesis. A large brain costs a body in important ways. Aiello and Wheeler proposed that changes in the brain promoted a reliance on meat protein in a much bigger way and possibly to hunting. This might have led to an increased life span. Kristin Hawkes took this a step further and developed what is called the grandmother effect. Why would human females have developed a long postreproductive life? Most other primates continue to have offspring right up until they die. Hawkes suggested that it would be advantageous to have grandmothers (and grandfathers?) around to look after the offspring while the prime adults were involved in food acquisition. As populations moved into larger ranges, this might have made the difference in survival.

The oldest fossil humans outside of Africa come from the remarkable site of Dmanisi in Georgia. Dated around 1.7 to 1.8 million years ago, Dmanisi has yielded dozens of fossil human specimens as well as pebble tools. One recent skull was extremely small, in the range of *Homo habilis*. How big a brain did humans really need to disperse out of Africa? A more recent discovery is a skull and mandible belonging to an individual who lost his or her teeth while still living. Was the survival of this individual proof of some kind of social welfare system this far back in time? If so, the Out of Africa 1 migration was carried out by humans who were markedly different from earlier African species.

Changing Climate after Two Million Years Ago

About 1.8 million years ago, the Quaternary period comprised two epochs: the Pleistocene (ca. 1.8 million years ago to 10,000 years ago) and the Holocene (ca. 10,000 years ago to the present day). The Pleistocene era is further divided into three phases: Lower/Early (1.8 million years ago to 780,000 years ago), Middle (780,000 years ago to 127,000 years ago), and Upper/Late (127,000 years ago to 10,000 years ago). The last two million years resulted in the evolution of several hominin species, namely *Homo erectus*, *H. neanderthalensis*, archaic *H. sapiens*, and humans (*Homo sapiens*). Soon after two million years ago, a member of the genus *Homo* migrated into Eurasia from Africa for the first time, and approximately 1.7 million years ago in East Africa there was a sudden technological shift from the Olduvan to the more sophisticated Acheulian techno-complex, generally associated with the speciation of *H. erectus*.

In the early part of the twentieth century A. Penck and E. Brückner proposed four major glacial periods or Pleistocene ice ages in Europe, later attempting to apply them globally. However, studies on deep-sea cores over the last several decades confirmed that earth had a much greater number of cold-warm phases than previously thought. Observations on this extensive marine sedimentary record, comprised of calcium carbonate skeletons of fossil foraminifera, resulted in a framework representing various oxygen isotope stages (OIS) and multiple but magnetic polarity reversals. Also in the early twentieth century, M. Milankovitch first proposed that primary attributes of earth's astronomical position in relation to the sun (or orbital forcing) vary cyclically over time and on different wavelengths, a widely accepted concept by the 1970s. The effects from these variable cycles, however, were and are geographically divergent,

and the respective periodicity or general durations of cold-warm and wet-dry phases also varied globally. For example, northern America and northern Europe witnessed the greatest effects of these cyclic glacial advances and retreats than other geographic zones.

The most intense cold peaks during the Plio-Pleistocene took place at 2.5 million, 1.8 million, 0.9 million, and 0.4 million years ago, all having major impacts on the terrestrial environment. The time between 75,000 to 12,000 years ago was cool and dry though interrupted by several interstadials, and the Last Glacial Maximum (LGM) was at its peak about 20,000 years ago. On the other hand, the Holocene, beginning at about 10,000 years ago, was essentially characterized by a global warming trend synonymous with the large-scale melting of glaciers. The Holocene is divided into three broad climatic stages: anathermal (cooler and wetter than today), hypsithermal (warmer and dryer than today), and medithermal (again cool and wet). In recent times, this significant increase in annual average temperatures has been thought to be an effect of both natural and anthropogenic factors. These periodic climatic oscillations and associated glacial cycles over the last two million years are also reflected in the global fossil pollen and faunal records, fluvial terrace systems, eustatic sea-level fluctuations, loess accumulation, and gradual expansion of arid zones, among other evidence.

Homo erectus in Asia

Homo erectus is the first member of our genus in Asia. Fossil remains come from China, northern Vietnam, Java (Indonesia), and the Republic of Georgia and are dated between 1.2 million and 200,000 years ago. Initially, they were described with names such as “Peking Man” (*Sinanthropus*) and “Java Man” (*Pithecanthropus*), but now they are all called *Homo erectus*. *Homo erectus* had a robust and low skull with a robust and straight brow ridge and a protuberance on the back of the skull. The lower jaw bore no chin, and the face was protruding forward (prognathism), though not as much as in australopithecines. The brain size ranged between about 700 cubic centimeters (Georgia) to over 1,200 cubic centimeters (China, Java). Seen from above, the vault of the Asian skulls is more strongly pear-shaped compared to the African skulls. *Homo erectus* inhabited more open environments, such as open woodlands and savannas.

The Indonesian fossils span almost the entire Pleistocene, ranging in age between 1.2 million years ago to as recent as 200,000 years ago, with a local relict population on Flores until 12,000 years

ago. The earliest Javanese *Homo erectus* fossil is from Mojokerto (Perning), coinciding with a land-bridge connection with the mainland. The latest Javan *H. erectus* is found at Ngandong. The Chinese fossils range between 830,000 and 240,000 years ago; the Vietnamese fossils fall within this range. The earliest Chinese evidence comes from Yunxian. Recent claims suggest that remains of an early *Homo* from Longgupo are much older and date to as early as 1.9 million years ago. The latest Chinese *H. erectus* comes from Hexian. The northern Vietnamese remains come only from Tham Khuyen, dated to 500,000 years ago. The fossils from Georgia, the westernmost Asian *H. erectus*, also come from one site (Dmanisi) only. The fossils were found in a layer with animals that lived between 1.8 million and 900,000 years ago.

Homo erectus was discovered during fieldwork in 1893 by the Dutch medical officer Eugène Dubois (1858–1940). On the banks of the Solo River near Trinil in East Java (Indonesia), he found an upper wisdom tooth and a skullcap. In size, they fell in between apes and humans. Initially, he ascribed his transitional ape-man, or “Java Man,” to *Anthropopithecus*, the old name for chimpanzees, literally man-ape. The thigh bone that he found a year later made him realize that his species walked upright and was more human than ape. Dubois made public his find in 1894 as the missing link between humans and apes. Appropriately, he named the fossil *Pithecanthropus erectus*, which means the “upright-walking ape-man.”

Soon after his publication, a debate started about the real nature of this *Pithecanthropus*. Key European scientists, including Richard Lydekker, Daniel John Cunningham, Sir Arthur Keith, and Sir William Turner, did not agree with Dubois. The fossils were considered to belong either to an ape or to a human, in the latter case a primitive one or even an idiot. Only American scientists, including Othniel Charles Marsh, reacted enthusiastically. Similar reactions would repeat themselves with every new discovery of a human ancestor.

A few years after Dubois’ announcement, Gustav Schwalbe compared the fossils from Java with modern humans, apes, and Neanderthals. For him, Neanderthals were the first humans, hence their name of *Homo primigenius*. He

Reconstructed skull of *Sinanthropus*, also known as Peking Man, first found near Beijing, China, in the 1920s and dated to roughly 250,000–400,000 years old. (Bettmann/Corbis)

concluded that *Pithecanthropus* should be placed between apes and Neanderthals. However, *Homo erectus* belongs to the more human-like species of the hominid lineage and is thus not a true intermediate form between humans and apes, despite Dubois' original designation. *Homo erectus* is not a missing link anymore.

In October 1926, a second trace of *Homo erectus* from Asia was recognized. Two human teeth were discovered by the Swedish paleontologist Carl Wiman among a collection of fossils. The material came from a limestone quarry near the village of Zhoukoudian (formerly Choukoutien), some 31 miles (50 kilometers) southwest of Beijing. The teeth were published under the new name of *Sinanthropus pekinensis*, which means China Man from Peking. It is commonly known as Peking Man, a name given by the American paleontologist Amadeus W. Grabau. Two years later, in November 1928, skull and jaw fragments were excavated, and the next year, in December 1929, Pei Wenzhong found a complete skull. Similarities with the Java Man and the Heidelberg Man were immediately recognized.

The reconstruction of the skull of *Sinanthropus* by Franz Weidenreich and Lucile Swan in 1937 was based upon the remains of several individuals. Unfortunately, the rich Zhoukoudian collection was lost during World War II, and afterward only a reconstructed skullcap was recovered. This cap, as well as casts of the lost skulls and fragments, was included by Ian Tattersall and Gary Sawyer in their reconstruction of the *Sinanthropus* skull in 1996.

The search for an early human at Zhoukoudian was inspired by a fossil human tooth found as far back as 1899 by one K. A. Haberer in an apothecary's shop in Beijing, sold as a "dragon's tooth." The tooth was determined by the German zoologist Max Schlosser as an upper left wisdom tooth of an unknown anthropoid primate. That was the spark that initiated deliberate excavations of dragon bone sites by Johan Gunnar Andersson and the Austrian paleontologist Otto Zdansky in the early twentieth century.

The third early discovery of fossils of *Homo erectus* was made by the Dutch geologist Carel ter Haar in 1931 along the Solo River on Java near the village of Ngandong. The remains of this "Solo Man" were described by Willem Op-

THE ODYSSEY OF THE ZHOUKOU DIEN FOSSILS

Zhoukoudien in China is one of the world's richest locales with fossils of *Homo erectus*. In September 1941 human fossils recovered from the site were due to be transported to the United States to safeguard them against the Japanese invaders. The plan involved a series of transports within Beijing, ending at the U.S. Marine Corps compound from where they would be sent to the port of Chingwangtao to embark USS *President Harrison*. This latter step never took place, as the ship was sunk by the Japanese before arriving at the port. What happened to the fossils is still a mystery, because none of the prevailing theories could be proven. One theory holds that the fossils were taken by marines on a train to Tientsin. The train was stopped by the Japanese, and the boxes became lost. According to another theory, the fossils were brought by the marines to a Swiss warehouse in Chingwangtao to be shipped to the United States. A third view holds that the fossils were taken home by a western sailor. His wife, eager to collect a reward, showed photographs of the fossils but was overwhelmed by unwanted publicity and disappeared from public view.

Unlike the Greek hero Ulysses, the Zhoukoudien fossils never returned home.

—Alexandra van der Geer

penoort (1881–1965) in 1932 as *Javanthropus soloensis* and considered a kind of modern human, based upon the gracile built and the presence of advanced tools. At present, Solo Man from Ngandong is considered the last *Homo erectus*, which lived until 200,000 years ago based upon datings of the associated fauna. The taxonomy and the correct dating of the Ngandong fossils is, however, still under debate, as is the case with so many early human remains.

Only five years later a Javanese fossil collector found the skull of a child some 6.2 miles (10 kilometers) from Mojokerto, between the villages of Pening and Sumbertengu, on February 13, 1936. This Mojokerto Child was described by the German paleontologist G. H. Ralph Von Koenigswald as *Homo modjokertensis* (now *Homo erectus*). Soon after, in the early 1940s, he found unusually large hominid remains at Sangiran. Based on the large size, he erected a new hominid genus for

► HOMO ANTECESSOR AT ATAPUERCA, SPAIN

Homo antecessor is at present the oldest European hominin. They lived 800,000 years ago in northern Spain. The species is based on an upper jaw and a frontal bone (ATD6-69) of a ten-year-old girl. It was found in 1994 by Eudald Carbonell i Roura and Juan Luis Arsuaga Ferreras in the Gran Dolino at Atapuerca. Remains of six more individuals were recovered from the same site and level, all dated to at least 780,000 years old. Traces on some of the bones seem to originate from cannibalistic behavior.

The face of this first European is modern, but the large teeth, low forehead, prominent browridge, and lack of a chin are considered primitive and are reminiscent of *Homo erectus*. The brain size is about 1,000–1,150 cubic centimeters. Based on the primitive traits, many scientists prefer to refer to it as either *Homo erectus* or *Homo heidelbergensis*.

The latter species was widespread throughout Europe between 600,000 and 250,000 years ago and is the ancestor of the Neandertals (*Homo neanderthalensis*). A problematic point is that the species *antecessor* is not based on a full-grown specimen but rather on a juvenile specimen.

Hardly a kilometer away, there is a second site at Atapuerca: Sima de los Huesos. These specimens are Neanderthals, dated to 400,000 years ago, and may represent a second migration into Europe.

Bermúdez de Castro, J. M., et al. “A Hominid from the Lower Pleistocene of Atapuerca, Spain: Possible Ancestor to Neandertals and Modern Humans.” *Science* 276 (1997): 1392–1395.

them: *Meganthropus*. At present, this genus, too, is regarded as *Homo erectus*.

The name *Pithecanthropus*, given by Dubois to the Java Man, was not entirely new to science. In 1874 Ernst Haeckel already published a human phylogeny in his *Systematische Phylogenie der Wirbeltiere (Vertebrata)* in which he included two extinct intermediate human species between modern humans and our supposed common ancestor with the apes. One of these two intermediates was *Pithecanthropus alalus*, meaning the speechless ape-man. It was precisely this “missing link” that Dubois hoped to find. Haeckel had proposed the submerged tropical continent Lemuria in the Indian Ocean as a place of origin. Thus, on October 29, 1887, Dubois gave up his university job to leave for the East Indies, present-day Indonesia. The East Indies had his special interest because they were not only tropical but also housed gibbons (a species of ape), which he knew were closely related to humans. Java drew his attention after the finding of the so-called Wajak skull (now *Homo sapiens*) near Tulangagung in 1888.

Based on a growing number of hominid fossils from Java and China and observed similarities between them, Von Koeningswald and Weidenreich concluded in 1939 that *Pithecanthropus*

and *Sinanthropus* should belong to one and the same species, for which they proposed the name *Homo erectus*. Later, the Javanese *Meganthropus*, the South African *Telanthropus*, the North African *Atlantropus*, and finally *Homo leakeyi* from Tanzania underwent a similar fate. African *Homo ergaster* and Georgian *Homo georgicus* are often included too. *Homo erectus* in the broad sense thus became a widely dispersed species. At present, two different views prevail concerning the taxonomic status of *Homo erectus*. One holds that there is one species only (the “lumpers”), while the other holds that there were up to a dozen contemporaneous *Homo* species during the Pleistocene (the “splitters”).

■ Introduction: The Appearance of Modern Humans

Following the appearance of our earliest ancestors in Africa more than two million years ago and the spread of *Homo erectus* across Africa and into Asia, the evolutionary history of our species becomes somewhat clearer. More fossil finds have been recovered from different parts of the world, and the larger sample of finds has made it somewhat easier to get a better picture of our subsequent evolution once our species left its homeland.

However, controversies remain. One of the most basic is concerned with the debate between supporters of the “multiregional” model of modern human origins versus those who ascribe to an “out of Africa” model. The former, which now has relatively few supporters, argues that our species, *Homo sapiens*, evolved from regional populations of *Homo erectus*. In contrast, the out of Africa model argues for a second migration of our species from Africa around 200,000 years ago. This movement spread our species into all continents except Antarctica by 15,000 years ago. Scientific opinion strongly supports this model.

What is interesting about this model is that humans moved out of Africa into some rather hostile environments. The great ices ages waxed and waned during much of this movement, and our ancestors had to cope with cold temperatures, limited resources, and difficult travel conditions. During this period, our species did not move into high northern latitudes simply because they were too great a challenge to the limited technologies these peoples carried. In fact, much of Europe was not occupied by *Homo sapiens* until just after 50,000 years ago.

However, a close relative, now extinct—*Homo neanderthalensis*—did in fact move into southern Europe some 300,000 years ago and persisted there until 35,000 years ago. The relationship between *Homo neanderthalensis* and *Homo sapiens* has been debated for more than a century. Early theories suggested that Neanderthals were on a direct line of evolution into *Homo sapiens*, at least in Europe. Yet other theories saw them as distant, somewhat dim, relatives that were very different from us in appearance,

behavior, and, importantly, intelligence. Yet it is now recognized that while Neanderthals were different from us, they were not that different. They survived in a very difficult environment for thousands of years with relatively simple stone tool technologies and primitive clothing. In this sense, they were well adapted to their surroundings until *Homo sapiens* made its appearance in Europe.

Just what led to the extinction of Neanderthals continues to be debated. Some have argued that our species hunted them into extinction whenever they were encountered. Others suggest that Neanderthals were submerged genetically through interbreeding, although there is little trace of their presence in the genes of modern Europeans and peoples in the Middle East, and comparisons of ancient DNA extracted from Neanderthal skeletons with that of modern humans show no evidence of interbreeding.

What seems to have led to the extinction of the Neanderthals are two factors: relatively small initial population size with little growth in numbers over time and competition with humans. This does not suggest that humans intentionally killed Neanderthals, but instead humans, with their more advanced technologies, more sophisticated division of labor, and better communication skills, were better able to compete for resources.

The Multiregional versus the Out of Africa Model

All specialists in human evolution agree that the earliest stages of human evolution took place exclusively in Africa. The first migration out of the continent occurred by 1.8 million years ago. Groups of *Homo erectus* spread into the Middle

East as far north as Dmanisi in Georgia and then spread out to colonize East and Southeast Asia. This process is generally referred to as Out of Africa 1. The oldest fossil remains in Europe are younger and come from two localities at the Sierra de Atapuerca, Spain. At the Gran Dolina, fragmentary human remains about 800,000 years old have been assigned to a new species, *Homo antecessor*. At the Sima del Elefante, or Pit of Elephants, researchers recently reported the discovery of a human jaw dated to 1.3 million years ago. Elsewhere in Europe, the earliest people are *Homo heidelbergensis* and are no more than 500,000 years old. *Homo heidelbergensis* had a brain and body size within the modern range but retained a number of archaic features such as a projecting face, large teeth, and a muscular postcranial skeleton. The best fossil record of *Homo heidelbergensis* comes from the Sima de los Huesos, or Pit of Bones, at Atapuerca where thousands of human bones have been recovered from the bottom of a deep shaft. Interestingly, only a few cave bear bones and a single stone tool (an Acheulean hand ax) accompany them. The fossils are roughly between 400,000 and 200,000 years old and represent the population that gave rise to the Neanderthals.

While few scholars dispute this interpretation of the initial colonization of Europe and Asia, what happened next is the subject of much debate. In Europe, the distinctive Neanderthal anatomy had developed by 200,000 years ago: a short stocky body built to stand extreme stresses and shortened distal limb segments (the radius and ulna of the forearm and the tibia and fibula of the lower leg). Neanderthals typically had long bullet-shaped skulls with an extension out the back, the famous occipital bun. They had low foreheads like *Homo heidelbergensis* and inflated sinuses and puffed-out nasal areas. Most of these features are said to be adaptations for regulating body temperature in an extremely cold, dry glacial environment. Neanderthals were present in Europe until as recently as 26,000 years ago. By then, however, there were anatomically modern *Homo sapiens* living right next door.

This differs significantly from the situation in Africa. There were never any Neanderthals here, only *Homo heidelbergensis* and then modern *Homo sapiens*. When a series of new dating

techniques was developed in the 1980s, it became clear that modern humans had appeared in Africa around 200,000 years ago and had a history almost as long as that of the European Neanderthals. So how were they related to one another? This debate has become increasingly strident as new lines of evidence appear. The new dates for African modern human sites were important, but more and more data was coming from the study of the genetics of living people. Initially, there were two opposing views of the origins of our own species. The traditional view is now referred to as the multiregional model. The other extreme is the Out of Africa 2 or replacement model. But in the ensuing years, more immediate positions have developed.

The multiregional model is also known as the candelabra or continuity model. It is associated with paleontologists such as Alan Thorne and Milford Wolpoff, who generally work on fossil human remains from East and Southeast Asia. But it goes back to Franz Weidenreich's earlier research on the *Homo erectus* fossils from Zhoukoudian, China. Multiregionalists believe that there was only one Out of Africa event, associated with *Homo erectus*. Local populations in Africa, Europe, and Asia evolved gradually from *Homo erectus* into modern humans. But there was sufficient mating and gene flow between different populations so that living people are genetically very similar. For supporters of this model, the outward or phenotypic differences between geographic groups, or races, could go back as far as *Homo erectus*. In addition, there is no need to define species for the stages of *Homo*. The different forms represent grades of humans, a continuous line from the earliest Out of Africa event.

What proof do multiregionalists cite in defense of their model? They describe anatomical traits that are supposed to be specific to different regional populations. For example, East Asians and aboriginal people in the Americas have a high incidence of congenital absence of third molars (wisdom teeth) and commonly have shovel-shaped incisors. These are said to be retentions from the first Asian *Homo erectus*. But it turns out that Neanderthals tend to have shovel-shaped incisors, and so do *Homo heidelbergensis* and modern humans in Africa. They

➤ TWO MODELS OF MODERN HUMAN ORIGINS

The traditional or multiregional model argues that after populations of *Homo erectus* dispersed out of Africa around 1.8 million years ago, they eventually each gave rise directly to modern humans. We still appear to be similar today worldwide because of gene flow between populations. The Out of Africa model agrees that *Homo erectus* was the

first hominid in Eurasia. But its proponents argue that there was a second Out of Africa migration sometime between 60,000 and 40,000 years ago that brought modern humans to Eurasia, where they replaced the indigenous populations.

—Pamela R. Willoughby

also point to Neanderthals who show modern like traits, such as the individuals at Vindika Cave in Croatia. Early modern humans at sites such as Mladeč in the Czech Republic have cranial traits linking them with Neanderthals (a supraorbital torus or shelf of bone above the eyes as well as an occipital hemibun, or bulge). There is also an Upper Paleolithic (Gravettian culture) child burial at Lagar Velho in Portugal that has a combination of Neanderthal and modern traits.

Out of Africa 2 is also known as (complete) replacement or the mitochondrial Eve model. It states that the only continent in which modern humans evolved from earlier humans is Africa. A speciation event occurred in a limited region of Africa, most likely in East Africa, producing a new species, *Homo sapiens*. Much later, descendants of this founder group expanded out of Africa, replacing all other groups in Eurasia. Supporters of this theory, including Christopher

Stringer, believe that human racial differences developed in the last few thousand years.

What proof do replacement supporters offer? The fossil evidence from Africa, along with the new dates, clearly shows the presence of anatomically modern people by 200,000 years ago. The earliest moderns are associated with Middle Paleolithic or Middle Stone Age flake tools, the kinds of things that Neanderthals were making at the same time. But another line of evidence comes from the study of mitochondrial and nuclear DNA in living people. In 1972 Richard Lewontin demonstrated the lack of significant genetic variation in human populations worldwide today. We now know that this reflects our recent common ancestry. The first study of human mitochondrial DNA showed that the greatest diversity was in African populations; all others seemed to be subsets of African variation. Mitochondrial DNA from fossil European Neanderthals

also confirms that they are significantly different from us; they remain our distant cousins and possibly a separate species.

There are more intermediate positions. Gunter Bräuer argues for replacement with hybridization, also referred to as the Afro-European *sapiens* model. This accepts the Out of Africa 2 idea but proposes that modern people retained the ability to mate with local people, producing hybrids. For him, the Vindija Neanderthals, Mladeč moderns, and the Lagar Velho child could all represent hybridization. Fred Smith supports a theory of assimilation. He argues that there were always more Africans living than non-Africans. Gene flow from Africans swamped Eurasians, giving an apparent African origin. A number of other researchers argue for a “mostly out of Africa” scenario. Henry Harpending’s “weak Garden of Eden” model accepts an African origin of modern humans but a much delayed migration out. Some kind of event caused a population bottleneck; this explains the sudden drop in archaeological and fossil sites toward the end of the Middle Stone Age. It was only when populations recovered that they could spread out of their center of origin.

The vast majority of fossil and archaeological data support an African origin of modern *Homo sapiens* sometime by 200,000 years ago. But their descendants do not spread out of the continent until thousands of years later. Why this was the case is the most important question in current archaeological and paleontological research in Africa. Many researchers point to the fact that early modern Africans made and used Middle Paleolithic stone tools, ones that were very similar to those of the European Neanderthals. But when modern humans appeared in Europe for the first time, just before 40,000 years ago, they had developed a series of new technologies and behaviors. These include organic tools (in bone, ivory, and antler), the earliest jewelry and art, and a focus on parallel-sided blade tools instead of flake tools, and there is evidence of increased planning depth in site use and resource acquisition. Put together, these Upper Paleolithic innovations show a real break with earlier people. So why did early African moderns fail to develop any of them? It may be that only the deteriorating climate characteristic of the late glacial period prompted technological change in African

Middle Paleolithic people. Or there could have been something more fundamental. Richard Klein of Stanford University thinks that modern humans developed symbolism and complex language at this time; this in turn prompted innovations and the Out of Africa 2 migration that took modern humans worldwide.

The Extreme Environments of Pleistocene

The Pleistocene is a geological epoch that until May 2009 was defined as spanning the period 1.8 million years ago to 10,000 years ago, but its time span has been redesignated by the International Commission on Stratigraphy to begin 2.6 million years ago. The revised date recognizes the advent of climatic cooling on a global basis. Together with the Holocene epoch, the last 10,000 years, the Pleistocene makes up the Quaternary period, the last of four periods that describe the earth’s geological history. The term “Pleistocene” derives from two Greek words, *pleistos* and *kainos*, that mean “most” and “new,” respectively. In terms of 4.54 billion years of earth’s history, the Pleistocene is both recent and short-lived. Nevertheless, it was a time of considerable environmental change associated with both natural and human activity. In the context of the latter it is unique, as many hominid ancestors and modern humans (*Homo sapiens*) emerged during this period, culminating in colonization of all the continents except Antarctica. In relation to natural change, the Pleistocene epoch was one of extremes, as warm and

cool climates alternated within climatic cycles, of which there were between 30 and 50. Such variations profoundly influenced soil processes and the distribution of plants and animals and raised and lowered sea levels. Why and how this occurred has been widely investigated, though many questions remain unanswered. The underpinning mechanisms relate to the pattern taken by the earth as it rotates around the sun, a factor that affects the amount of heat energy received at the earth's surface, and the global biogeochemical cycle, which had a much greater atmospheric pool during warm stages. Understanding such change and rates of change is especially important in the context of modern global warming and the necessity of understanding the mechanisms that underpin climatic change.

There is a wealth of information pertaining to the Pleistocene in the earth's environmental archives (e.g., ocean sediments, lake sediments, glacial deposits, peat, paleosols, ice caps, and glaciers). Biological, chemical, and physical evidence has facilitated a detailed reconstruction of this dynamic epoch. Of particular importance are oxygen-isotope signatures obtained from marine sediment and polar ice cores. The ratio of two isotopes of oxygen, ^{18}O to ^{16}O , is temperature dependent and is used as a proxy for reconstructing temperature/climate change. The lighter isotope, ^{16}O , is preferentially evaporated from the oceans, which are colder during periods of low temperature. This means that the heavier isotope ^{18}O becomes enriched in the water. The prevailing ratio is reflected in the shells (known as tests) of marine organisms, notably foraminifera, as they absorb oxygen-containing carbonate (CaCO_3) from seawater. The shells become incarcerated in sediment and thus provide a record of oxygen isotope variation, and hence of climatic change, over time. Water that accumulates as ice at the poles also comprises oxygen isotopes in ratios that vary climatically; during warm stages additional heat causes preferential evaporation of ^{18}O , which results in more ^{18}O relative to ^{16}O . The marine sediment and ice core records are thus mirror images. This methodology has been applied to widely distributed marine sediment cores as well as to numerous ice cores from the poles and high-altitude ice caps so that global patterns of Pleis-

tocene climatic change have been reconstructed. The oxygen-isotope data have been augmented by deuterium and carbon dioxide concentrations from ice cores, though these records extend at best as far back as circa 800,000 years.

Such reconstructions have revealed the pattern and characteristics of climatic cycles during the Pleistocene. Broadly, the cycles from 2.6 million to 0.8 million years ago lasted circa 40,000 years, with limited ice cap growth at high northern latitudes during the cold parts of the cycle. The cycles from 0.8 million years ago to the present lasted circa 100,000 years, with large-scale ice cap formation at high northern latitudes. Of the ten glaciations during this latter period, the last two were particularly extensive, with ice sheets several thousand feet deep covering much of Scandinavia and Eurasia and extending as far south as the Great Lakes in North America in addition to extensive glaciation in the Alps, Andes, Urals, and Himalayas. Each glacial stage lasted circa 80,000 to 100,000 years, with intervening warm stages being short-lived at circa 15,000 to 20,000 years. Although global temperatures were on average 18–20 degrees Fahrenheit (10 to 11 degrees Celsius) lower during glacial stages, the high latitudes cooled considerably more than the low latitudes. Conditions during the warm stages were similar to those of today (pre-1950s) or perhaps a little warmer. Furthermore, the shift from cold to warm conditions was relatively rapid, taking just 1,000 to 2,000 years. It is also important to note that climate was not uniform within the cold and warm stages of each cycle, but highs and lows were never as accentuated as those between warm and cold stages.

The major warm-cold shifts were relatively short-lived in geological terms, yet they had profound effects on global biogeography and possibly on early human history. First, ice advance displaced plants and animals, which reacted at the species level to climatic change. This means that new configurations of organisms occurred as soils and sea levels (which affected land links) altered and altered again. The impact is more obvious in high latitudes due to changes in the extent of ice, but it was significant in middle and low latitudes as reduced temperatures affected forest, savanna, grassland, and desert ecosystems,

which changed in distribution, extent, and composition. Second, mountain areas at all latitudes experienced major vegetation shifts (e.g., the tree line in the Andes was depressed by up to 3,000 feet [914.4 meters] during cold stages). The presence of land bridges during glacial stages facilitated plant and animal migration (e.g., the colonization of Mediterranean islands by plants and animals from Europe, Asia, and Africa), which has contributed to island biodiversity. It is also possible that Pleistocene climatic shifts prompted the movement of first *Homo erectus* and later *Homo sapiens* out of Africa, while the Bering land bridge between Asia and the Russian Far East facilitated the human colonization of the Americas, though when this occurred remains controversial.

Africa—*Homo heidelbergensis*

Homo heidelbergensis is a species of human defined by Otto Schoetensack (1908). He used the Mauer mandible as the type specimen, which

had been recovered from a quarry near Heidelberg, Germany. This species is also referred to as archaic *Homo sapiens* and represents the last common ancestor of European Neanderthals and African modern humans. It ranges in time from around 600,000 to 200,000 years ago and is found throughout Europe, Asia, and Africa. A single frontal bone has also been recovered at Zuttiyeh in Israel.

Homo heidelbergensis has a body structure that is quite similar to that of living humans. The skull has a large, round brain case within the modern size range (1,000–2,000 cubic centimeters). The face is prominent and projecting, with large teeth, and many individuals have an M-shaped arch or supraorbital torus over the eyes. Specimens assigned to *Homo heidelbergensis* vary greatly. Many show a mix of features seen in *Homo erectus* and *Homo ergaster* and more recent humans (such as modern humans and Neanderthals), clearly showing their role as transitional between the two groups. Others, especially those from Africa, mix archaic and anatomically modern features.

There are a number of sites in Africa from which remains assigned to *Homo heidelbergensis* have been recovered. They include a partial skull, face, and lower jaw (with a chin) from Rabat in Morocco and a partial skull from the nearby site of Temara. A number of skulls have been collected at Jebel Irghoud; these are either *Homo*

➤ WAS *HOMO HEIDELBERGENSIS* THE FIRST HOMININ IN EUROPE?

Homo heidelbergensis was possibly the first European. They originated in Africa and spread north into Europe around 500,000 years ago. When people arrived in Europe is quite contested. Anthropologists Wil Roebroeks and Thijs Van Kolfschoten argued that no one lived here before 500,000 years ago. Recent research at the Atapuerca site in Spain has shown that this conclusion was premature. The Gran Dolina or Trinchera Dolina has fragmentary human remains and pebble tools in sediments with reversed magnetic polarity. This makes them at least 780,000 years old. Based on this, Robin Dennell and Wil Roebroeks concluded that early humans must have reached Mediterranean Europe by this time. But then they

went on to say that no one lived in the part of Europe that really mattered until much later.

Atapuerca has yielded even more surprising results. A human mandible at a new locality, the Sima del Elefante, or Pit of the Elephant, is dated to 1.2 million years ago. But for many paleoanthropologists, the most important site at Atapuerca is the Sima de los Huesos, or Pit of Bones. This is a large underground cavern in which thousands of fossil bones have been recovered; they are between about 200,000 and 400,000 years old. Except for some cave bears, they are all human, people who were well on their way to becoming Neanderthals.

—Pamela R. Willoughby

► HOMO ERECTUS IN EUROPE

One of the most fascinating questions about the first peopling of Europe was whether or not *Homo erectus* ever settled on the continent. The oldest human fossils in Europe come from the Sierra de Atapuerca in northern Spain. A partial mandible was recently discovered in the Sima del Elefante and dated to around 1.2 million years ago. The next oldest are fragmentary remains from the Gran Dolina or Trincheras Dolina that have been assigned to *Homo antecessor*. These come from sediments with south-facing magnetic polarity and are at least 780,000 years old. But neither of these fit the description of *Homo erectus*.

Homo erectus (also known as *Homo ergaster*) first appears in Africa around 1.8 million years ago and spreads out of Africa into Asia around 1.7 million years ago. The oldest site outside of Africa is Dmanisi in Georgia; other localities on the island of Java in Indonesia could be almost as old. Less than one million years ago the same species is found at Zhoukoudian, the Peking Man site on the edge of the modern capital of Beijing. *Homo erectus* is defined by a number of cranial features including an angular skull with a sharp occipital angle, a sagittal ridge, and flattened parietal bones (giving the skull the appearance of a gabled house). They have a large projecting face, with

teeth larger than those of later humans. Their brain volume or cranial capacity ranges between 750 and 1,250 cubic centimeters (cc), with an average of 1,000 cc. This contrasts with the 1,000 to 2,000 cc (and average of 1,350 cc) for modern humans and *Homo heidelbergensis*.

Outside of Atapuerca, the oldest fossil humans come from sites like Ceprano in Italy. At both localities, they are associated with core and flake tools, not the Acheulean bifaces of the subsequent species, *Homo heidelbergensis*. The Ceprano skull, around 800,000 years old, is intermediate in form between *Homo erectus* and *Homo heidelbergensis*. While its cranial shape is similar to *Homo erectus*, its size is within the range of *Homo heidelbergensis*.

Most of the earliest fossil human remains in Europe date to 500,000 years ago or younger. They tend to be associated with Acheulean tools, but others are associated with flake and core tools. Few of them resemble the classic *Homo erectus* of Africa or Asia. If it was not for Atapuerca, one would be forced to conclude that no one reached Europe until around 500,000 years ago. Perhaps Atapuerca represents an early limited movement of humans out of Africa, possibly across the Strait of Gibraltar.

—Pamela R. Willoughby

heidelbergensis or modern humans. Excavations at the Paleolithic cave of Haua Fteah in Libya produced a mandible fragment, and a skull cap was collected at Singa in the Sudan. One cranium was found at Bodo in the Middle Awash of Ethiopia; it is around 600,000 years old. At Omo-Kibish locality 2, a skull was collected in 1967 that has recently been redated to almost 200,000 years ago. Other finds in the Kibish Formation are of similar age but are anatomically modern. One fragmentary cranium was found at Melka Kunturé and another at Diré Dawa (or Porc Epic Cave), both in Ethiopia. At East Turkana in Kenya, remains of *Homo heidelbergensis* have come from Eliye Springs, Guomde (KNM-ER 3884), and other localities. These are dated to between 200,000 and 300,000 years ago. Two mandibles have been collected from the Kapthurin Formation at Lake Baringo and a single cranium from the Ndutu For-

mation at Olduvai Gorge in northern Tanzania. The famous australopithecine site of Laetoli has also produced LH 18, a cranium from the Ng'oloba Formation. From an open-air site near Lake Eyasi, a single skull and other remains have been collected as well as three molars from the nearby Mumba Cave. In 1921, researchers reported several partial skeletons from Kabwe (or Broken Hill), Zambia. In South Africa, archaeological sites such as the Cave of Hearths (a mandible fragment), the Florisbad hot springs (a single skull), and Saldanha (or Elandsfontein or Hopefield) (another skull) have also produced fossil humans. The oldest *Homo heidelbergensis* fossils are usually associated with Late Acheulean tools (bifaces plus a range of Levallois flake tools). Many others belong to the Middle Paleolithic or Middle Stone Age.

Homo neanderthalensis

The first *Homo neanderthalensis* fossils were discovered at Engis Cave, Belgium, in 1929–1930, and in Forbes' Quarry, Gibraltar, in 1848, but their significance was not recognized as such at the time. It was the skullcap and postcranial bones found by quarry workers at the Feldhofer Cave in Germany's Neander Valley in 1856 to which most authorities trace the discovery of the Neanderthals. The large brow ridges, low forehead, and bulging sidewalls of the skullcap alongside the very robust limb bones were clear indications that the bones were not from a modern human. These features led the Irish anatomist William King to suggest that the fossils belonged to an extinct human species he called *Homo neanderthalensis*.

As more fossils were discovered, our understanding of the morphology of these hominins grew. By 1920 Neanderthal remains (and their artifacts) were found in the Belgian cave sites of Trou de La Naulette and Spy; in Sipka Cave in Moravia (Czech Republic); in the French cave sites of La Chapelle-aux-Saints, Le Moustier, La Ferrassie, and La Quina; and at the Krapina Rockshelter near Zagreb, Croatia. The decades that followed yielded many more fossils but also demonstrated that the range of the Neanderthals extended from western Europe into Asia. Early West Asian cave sites include Tabun, Kebara, and Amud in Israel; Dederiyeh in Syria; and Teshik-Tash in Uzbekistan (west-central Asia). The addition of Shanidar Cave in Iraq and several Iranian sites has pushed the eastern extent of their territory even farther.

Determining the age of the Neanderthal fossils is somewhat difficult, as most fall near the practical limit of radiocarbon dating. The youngest remains date between 40,000 and 30,000 years ago, using a combination of thermoluminescence (TL), uranium-series (U-series), electron spin resonance (ESR), and radiocarbon (^{14}C) dating methods. The geological age of the oldest sites is uncertain, as the deposits encasing the bone of nine individuals at Ehringsdorf, Germany, were formed between 242,000 and 186,000 years ago based on U-series and ESR dates, but the associated plant and animal remains suggest a Last Interglacial age between 127,000 and 71,000 years ago. TL dates between 190,000 and 159,000 years ago were also received from the Biache-Saint-Vaast site in France, however, which supports the appearance of *Homo neanderthalensis* around 190,000 years ago or before. Most Neanderthal fossils date between 127,000 and 50,000–35,000 years ago, placing them in the Last Interglacial and the early part of the Last Glaciation.

The abundant *Homo neanderthalensis* fossil record makes it relatively easy to characterize their skeletal morphology. The thin-walled cranium is long and low and has an oval shape, with the maximum breadth midway up the braincase. One of the most distinct features of the Neanderthal skull is the occipital bun, or chignon, on the back of the skull where the lambdoid and sagittal sutures meet. The endocranial capacity of the skulls range from 1,245 to 1,740 cubic centimeters (cc) and average around 1,520 cc, compared to 1,340 cc in living people. The front of the skull reveals a low frontal area with a pronounced continuous browridge that generally forms a double arch above the large eye orbits. The nasal aperture and cavity are also oversized. The lack of a chin is a typical feature, as are the large cheekbones.

The molars of the Neanderthals are smaller than those from earlier *Homo* species, overlapping in size with the teeth of modern humans, but their incisors are larger and often shovel-shaped. Many of these front teeth exhibit distinctive rounded wear on the inside and are more worn than the cheek teeth and canines. There is a discernible gap, called the retromolar space, between the lower third molar and the

ascending ramus of the mandible (lower jaw bone). Moreover, the sigmoid notch in the ascending ramus is larger, farther back, and asymmetrical when compared to a *Homo sapiens* mandible.

Postcranial elements reveal uniquely Neanderthal traits as well. The cervical vertebrae have long horizontal robust spines and enlarged neural canals that enclosed the spinal column. The ribs are also very thick and curve out from the spine to create a broad chest. The arm and leg bones have thick shafts that reflect an ability to endure long periods of intensive use. The muscle and ligament attachment areas on the bones are extremely large and well developed, which, together with the bowed shape of the radius and femur, signal extraordinary muscular strength. Neanderthal fingers are larger and rounder than those of modern humans, also revealing increased strength and a powerful grip.

Homo neanderthalensis is easily distinguished from all other *Homo* species based on these and other morphological traits. They were a powerfully built hominin that had a large, long, oval skull with a heavy browridge over large, deep-set eyes and a large nose. Their great breadth but their shorter stature and limb size may have resulted from an adaptation to the cold climate in which they lived. This could also explain their larger cranial capacity, which may be linked to greater metabolic efficiency. What remains difficult to assess is the language ability of these humans. The relatively flat cranial base and elevated larynx suggests that they could not make the full range of words and sounds as modern humans can, but the large neural canals imply control over the phonetically significant movements of the chest.

Recent advances in genetic studies have clarified the relationship between *Homo neanderthalensis* and *Homo sapiens*. Mitochondrial DNA extracted from Neanderthal fossils confirmed that the two species shared a common ancestor, between 690,000 and 550,000 years ago, diverging along separate evolutionary lines after that. They did, however, live in the same regions just before the Neanderthals became extinct, but it is very unlikely that the two populations interbred. The cause of their extinction

remains a matter of debate, but many scholars agree that they were behaviorally inferior to the newly arrived *Homo sapiens*. It is likely that they were outcompeted for food and other valued resources.

Homo sapiens in Africa

Our own species, *Homo sapiens*, was defined by the Swedish botanist Carolus Linnaeus in the tenth edition of his *Systema Naturae* (1758). There was no real description or type specimen or discussion of what this species represented. Much later, the American vertebrate paleontologist Edward Drinker Cope (1840–1897) left his body to science with the express wish that he could be designated the type. But his numerous skeletal pathologies, reportedly the result of syphilis, made him an unlikely candidate.

Like Linnaeus, modern anatomists and biologists have had difficulty defining what it means to be an anatomically modern *Homo sapiens*, especially in relation to our most recent direct ancestor, *Homo heidelbergensis* (formerly archaic *Homo sapiens*). Besides meaning people who are skeletally like us today, there are a few criteria that define us. One is our large round skull. Modern brain volumes range from 1,000 to 2,000 cubic centimeters (cc), with an average of 1,350 cc. The face is tucked in below the forehead and does not jut out. There is a chin or mental eminence on the lower jaw. Muscle attachments on both the skull and the rest of the body are reduced relative to earlier humans. Likewise, the entire skeleton is much lighter than earlier.

There have long been heated debates about the origins of modern *Homo sapiens* and even about what it means to be modern. In the 1980s around the same time as the Out of Africa 2 model became popular, geochronologists

LOCATIONS OF AFRICAN SITES WHICH HAVE YIELDED FOSSIL REMAINS OF *HOMO HEIDELBERGENSIS* AND/OR EARLY MODERN *HOMO SAPIENS*

developed a battery of new dating techniques that profoundly changed our image of modern human origins. These include electron spin resonance (of mollusks, tooth enamel, and corals), optically stimulated luminescence (of sediments), and thermoluminescence (of burned flint stone tools). These were first applied to Middle Paleolithic sites in the Levant, which contained either modern humans or Neanderthals. The surprise was that the modern human sites (the Mughareet es Skhūl and Jebel Qafzeh) were older than the Neanderthal ones. When African sites were dated in the same way, the old-

est modern humans became almost 200,000 years old. This date coincided with the beginning of the Middle Paleolithic or Middle Stone Age, not with the Upper Paleolithic (or Later Stone Age) as was expected. Modern humans appeared to have been living in Africa as long as Neanderthals had lived in Europe.

A number of African sites contain fossil remains of *Homo sapiens* or *Homo heidelbergensis*. Most of the early modern ones, however, belong to the Middle Paleolithic or Middle Stone Age and are over 100,000 years old. The archaeological and fossil record decreases remarkably

► MOLECULAR BIOLOGY AND THE EVE HYPOTHESIS

Human cells, like those of all living organisms, contain two sets of DNA strings, one in the nuclei and the other in the mitochondria, the organelles that generate energy. Both DNA types can be used to trace back our common ancestry. Mitochondrial DNA is inherited only from one's mother, while nuclear DNA from the Y chromosome is inherited only from one's father. All living humans' female line ancestry can be traced back to a single female (Mitochondrial Eve), who lived between 200,000 and 140,000 years ago. Our male line goes back to a single male (Y-chromosomal Adam) at around 60,000 years ago.

One advantage of using mitochondrial DNA is that it mutates relatively fast, unlike nuclear DNA. In this way, it provides a fast-ticking molecular clock. The meaning of all this is that even popula-

tions that became separated from each other not longer than just a few hundred thousand years ago have already built up detectable genetic differences in their mitochondrial DNA. The longer the separation between populations, the more genetic differences there are. With the use of mitochondrial DNA, the time of divergence can be calculated.

Another advantage of using mitochondrial DNA over nuclear DNA is that it is inherited through the maternal line only. In nuclear DNA, maternal and paternal genes may become mixed.

The Mitochondrial Eve hypothesis was launched in 1987 by Allan Wilson and colleagues. By analyzing mitochondrial DNA, they were able to place our common ancestor with the African great apes at some 200,000 years ago.

—Alexandra van der Geer

around 70,000 to 30,000 years ago, just as the Out of Africa 2 migration is supposed to begin. Richard Klein of Stanford University posits that African people were anatomically modern or near modern during the Middle Stone Age. But because their artifacts are similar to those of European Neanderthals, he believes that Africans only became truly modern at the start of the Later Stone Age. At this time, he argues, they developed complex language and cultural behavior. This in turn led to the great migration out of Africa and to the replacement of the indigenous people of Eurasia. It is hard to test this idea, but transitional sites are beginning to appear in East Africa and in the interior of South Africa. My own research in southern Tanzania has produced two already (Mlambalasi and Magubike rockshelters near Iringa City).

While there are many places with early modern human remains in Africa, these remains are quite fragmentary. In Morocco, some cranial fragments were recovered at Temara; these belong to *Homo heidelbergensis*. Early modern human remains have been found at Dar es Soltan, El Mnasra I (or the Smuggler's Cave), and Jebel Irhoud. All of these are associated with Mousterian or Aterian stone tools. The Mousterian is the typical North African Middle Paleolithic, dominated by Levallois tools. The Aterian is an

industry that belongs to the late Middle Paleolithic and is marked by tools with retouched stems or tangs. In Libya, the deep cave site of Haua Fteah yielded a single lower jaw; it is *Homo heidelbergensis* and is associated with Mousterian tools. In Egypt, an anatomically modern child skeleton was recovered from a Middle Paleolithic chert mine at Taramsa 1. Two partial skeletons come from Nazlet Khater 2. A single *Homo heidelbergensis* skull cap comes from the site of Singa in the Sudan.

In Ethiopia, *Homo heidelbergensis* skulls have been recovered from Bodo in the Middle Awash and from the Kibish Formation at Omo. *Homo sapiens* fossils come from Diré Dawa (a mandible) and Omo Kibish (a skull and partial postcranial skeleton from one locality and a forehead fragment from another). Three skulls were found at Herto, and a number of other cranial remains were found at Aduma, both in the Middle Awash. In Kenya, *Homo heidelbergensis* remains come from a number of localities on the east side of Lake Turkana and from the Kapthurin Formation at Lake Baringo. A fragmentary modern *Homo sapiens* skull was found at Lukehya Hill in the south. In Tanzania, a number of localities in the north (Olduvai Gorge, Laetoli, next to Lake Eyasi, and at Mumba Cave) have produced remains of *Homo heidelbergensis* or

Homo sapiens. My own fieldwork in southern Tanzania has produced Middle Stone Age human teeth in one rockshelter (Magubike) and one or more Later Stone Age human burials at another (Mlambalasi).

In Zambia, *Homo heidelbergensis* remains were excavated in the 1920s at Kabwe. Some teeth and postcranial fragments were recovered much more recently from Mumbwa Cave. South Africa has many sites with *Homo heidelbergensis* remains, either Middle Stone Age (Florisbad) or Acheulean (a mandible at the Cave of Hearths and a skull from Saldanha). *Homo sapiens* remains come from Middle Stone Age contexts at Klasies River, Die Kelders 1, Blombos Cave, Hoedjiespunt I, Sea Harvest, Border Cave near Swaziland, and Equus Cave near the early human site of Taung.

While it is clear that *Homo sapiens* had a very early African origin, the exact processes behind our emergence remain to be determined.

Homo sapiens in Asia

There are two theories regarding the biological evolution of modern humans in the Old World, and Asia plays a crucial role in both. The first is the Multiregional theory, which posits that modern humans evolved more or less at the same time in different parts of the Old World from their respective predecessors in those respective regions (e.g., Chinese *Homo sapiens* from Chinese *Homo erectus* populations). The second theory is known as the Out of Africa or Replacement hypothesis, which emphasizes the evolution of modern humans in Africa and their subsequent dispersal into different parts of Eurasia and leading to the presumed gradual replacements of earlier *Homo erectus* or *Homo heidelbergensis* populations. While there is convincing multidisciplinary evidence that *Homo sapiens* may have

replaced preexisting *Homo neanderthalensis* populations in Europe during the Upper or Late Pleistocene, our understanding of the biological and behavioral evolution of modern humans in Asia remains highly ambiguous. Both theories have their respective professional advocates, including numerous physical anthropologists, Paleolithic archaeologists, and geneticists. One fact is clear, however: the oldest known anatomically modern human fossils currently come from Ethiopia and are 190,000 years old.

Asia is a large geographic area comprising various types of ecosystems and climatic conditions. The region is well known for its lengthy record of human occupation since the Early and Middle Pleistocene: Dmanisi and Ubeidiya in West Asia; Nihewan Basin, Zhoukoutien, and Chongok-ni in northern and East Asia; and Sangiran, Modjokerto, and Mata Menge in Southeast Asia. In recent decades, there have been an increasing number of archaeological and paleontological discoveries related to the occupational history of modern humans in the region. This evidence comes from a large number of sites from almost all geographic zones of Asia, though their respective ages vary considerably. Ultimately, the modern human paleontological record in Asia following the initial appearance of the species in Africa is significantly incomplete.

Various types of lithic or stone tool assemblages are associated with modern human fossils in different parts of Asia. These regional assemblages are indicative of indigenous technological development and ecological adaptations but also share affinities (at times) with similar assemblages from Africa and Europe. These tool kits include specialized artifacts such as prepared cores, blades, burins, projectile points, bone harpoons, points, and scrapers. Associated with the lithic evidence are related behavioral traits such as long-distance transport and curation of exotic raw materials, symbolic behavior such as cave/rock shelter painting, engraved or incised artifacts, the ritualistic use of ochre and other pigments, greater ecological adaptive strategies including site selection and land use, tool hafting, the utilization of other raw materials, self-adornment, and an increase in human burials often with grave goods. Some Asian examples of sites that have variably yielded human fossils,

stone tools, and other associated evidence include Liujiang and Upper Cave (Zhoukoudian) in China, Patne and Bhimbetka in the Indian subcontinent, and Kota Tampan and Niah Cave in Southeast Asia. All collective changes in technology and behavior are generally thought to reflect a gradual but distinct shift from the Middle Stone Age/Middle Paleolithic to the Late Stone Age/Upper Paleolithic. A unique feature of the Asian record is that large parts of the population retained expedient tool kits up to the Holocene, unlike the marked and visible change in lithic technomorphology in Europe and Africa.

In the Near East, evidence from over 30 individuals at Skhul (120,000–40,000 years ago) and Qafzeh (100,000–90,000 years ago) indicates the presence of early modern populations. In this region, however, there has been much debate regarding the identification of specific specimens to specific taxa (*H. sapiens* vs. *H. neanderthalensis*), and various theories have been put forward regarding admixture, gene flow, resource competition, seasonal population movements, interbreeding, and associated climatic, ecological, and faunal factors for the evolution of modern humans and the biological extinction of Neanderthals in the region. Based on published data, researchers have recently argued that modern humans arrived in South Asia at an earlier time than they arrived in Europe. Indeed, South Asia has often been depicted in publications as representing an intermediate geographic zone for early and modern *Homo* groups dispersing from East Africa to Southeast and East Asia along a southern coastal route. Some key sites in the Indian subcontinent that have yielded evidence of modern human occupation in the form of stone tools and human fossils are Sangaho Cave and Site 55 in Pakistan, Kurnool Caves and Attirampakkam in southern India, and Badatomba-lena and Fa Hien Caves in Sri Lanka.

In contrast, the evidence from East and South Asia is not as abundant as in other parts of the Old World. The East Asian evidence is utilized by proponents of the Multiregional theory to support biological continuity or evolution of modern humans from the archaic forms. The East Asian (i.e., Chinese) evidence appears to be comparatively more secure in terms of context and chronology than the Southeast Asian evidence. Another problem with some of the South-

➤ THE “DEEP SKULL” AT NIAH CAVE

The site of Niah Cave, located in northern Malaysian Borneo (part of Sarawak Island in Southeast Asia), contains a thick sequence of sediments ranging from the Late Pleistocene to the Holocene in age. The cave roof is about 246 feet (75 meters) from the cave floor, and the entire area totals almost 24.7 acres (10 hectares). Large-scale excavations in the 1950s and 1960s yielded over 200 burials of modern humans, including a cranium popularly known as the “Deep Skull” that was found in association with stone tools and charcoal. The significance of this young female specimen, which was recovered with a femur, nonhuman faunal remains, and a lithic flake, is highlighted by its possible age between 42,000 and 45,000 years ago. If this age estimate is accurate (the context of the specimen is controversial), then the “Deep Skull” and associated bones may represent one of the oldest modern human fossils in this region of Australasia.

—Parth Chauhan

east Asian evidence is the ages for some specimens labeled as *Homo erectus* at Ngandong: 53,000–27,000 years ago. In other words, if the age and taxonomic identification are correct, what role did these exceptionally young *Homo erectus* groups play in the evolution and/or arrival of modern humans in this part of Asia, especially if the latter were already occupying other parts of Asia and the Old World? A less contentious but equally significant find comes from Dali (ca. 200,000 years ago) in the Shaanxi Province in China, which yielded a cranium without teeth and has been employed to support evolutionary continuity from archaic human populations in this region. Under current circumstances, it is clear that the human evolutionary history of Asia was quite complex, and neither the Replacement nor the Multiregional hypothesis is currently supported or refuted completely.

***Homo sapiens* in Europe and the Middle East**

The migration of *Homo sapiens*, modern humans, into Europe and the Middle East out of Africa developed out of a climatic change that allowed migration northward and gradual adaptation that permitted survival in the harsher

northern climes. It is estimated that between 60,000 to 40,000 years ago, modern humans dispersed northward into Eurasia after thousands of years of gradual evolution in regions of central Africa. The centrality of the Middle East as a crossroads from Africa to both Asia and Europe allowed for the migration of *Homo sapiens* into that region for settlement purposes. Within 20,000 years, *Homo sapiens* occupied areas of Eurasia previously inhabited by *Homo erectus* 1.8 million to 1.4 million years ago. In the midst of this migration, *Homo sapiens* settled in both Europe and the Middle East, competing at first with Neanderthals for resources. While first settling and adapting to the harsh northern latitudes, modern humans eventually settled in the warmer southern regions of Europe.

Climatic changes during this period of migration are characterized by a gradual warming of the northern latitudes in the period following

➤ RELATIONS BETWEEN *HOMO SAPIENS* AND NEANDERTHALS

Do *Homo sapiens* and Neanderthals belong to the same or different species? Ever since the first Neanderthal was recognized as an extinct human, this has been the key research question. For some researchers, Neanderthals are just a geographic subspecies of *Homo sapiens*; if so, they would be classified as *Homo sapiens neanderthalensis*. This would make them capable of interbreeding with "modern" Upper Paleolithic Cro-Magnons whose ancestors were African. Other researchers stress the anatomical differences between the two groups and the fact that Cro-Magnons seemed to have replaced Neanderthals in Europe between 40,000 and 26,000 years ago. For them, there is no clear evidence of interbreeding or of the evolution of modern humans directly from European Neanderthals. On the other hand, there is growing evidence of cultural interaction and trade between the two groups. Relatively recent Neanderthals were producing jewelry and bone tools, just as Cro-Magnons were. But it looks like this happened only after the arrival of modern people. Was this a sign of acculturation to a new Upper Paleolithic world? If so, did it alter the behavior of both groups? Looking at the evidence from the Middle Paleolithic in the Levant, anthropologist John Shea argues that both groups were affected in a significant way.

Both Neanderthals and moderns are descended from *Homo heidelbergensis*, so they represent evolutionary cousins. Genetic studies of living people and Neanderthals confirm this. But the first modern people in Africa created the same kinds of artifacts as Neanderthals did: Levallois and Mousterian points and scrapers. They also lived at the same time. So if the first "modern" people were African and Middle Paleolithic, then why were they the ones who became the ancestors of Cro-Magnons and replaced Neanderthals in Europe? This is a question that also remains unanswered.

the last Ice Age. The necessity to migrate north was perhaps due to scarcity of resources following long periods of increasing aridity. However, the gradual warming in the north allowed people to slowly migrate northward through what had previously been frozen wasteland or land expanses covered by glaciers. Vegetation and herds of animals suitable for hunting had also migrated northward due to climatic fluctuations that permitted their survival in northern latitudes. The evolving hunter-gatherer society that characterized this period of human history illustrated that northward migration was pivotal for survival to some segments of the population that had inhabited Africa.

Gradual climate change, while allowing for humans to inhabit Europe and the Middle East, was still characterized by cold weather and the living conditions associated with it. Humans in these regions were forced to adapt to the weather conditions in order to live a comfortable day-to-day existence. This created the need for technological adaptation in the form of tailored fur clothing, the use of lamps, and the ability to heat shelters for warmth. Other forms of technological advances during this period include tools for trapping small animals and for acquiring birds and fish. These adaptations allowed modern humans in Europe to survive in their new regions of habitation in this period of extreme climatic fluctuations.

According to archaeological estimates, modern humans already inhabited the Levant in the Middle East as early as 120,000 to 90,000 years ago in an archaic form of *Homo sapiens*. This find made between 1987 and 1992 in Skhul and Qafzeh represents not part of the northern migration of the later period but rather part of the gradual dispersal of the African populations into adjoining regions. This recent find underlines the proximity of the Middle East to Africa and indicates that there were precursors on the pathway that modern humans were to take in the later northward migrations between 60,000 to 40,000 years ago into Europe and Asia through the Middle East.

The first humans to inhabit Europe are believed to be from the East European Plain in what is now modern Russia and parts of Eastern Europe. Archaeological excavations in the region illustrate the level of cultural sophistication

➤ SKHUL AND TABUN

Skhul and Tabun, two neighboring caves at Israel's Mount Carmel, beside the Mediterranean Sea, contain extensive occupations with Neanderthal Mousterian lithic remains and burials as well as later occupations. The Mousterian lithic artifacts in the two caves are very similar to each other, flaked on flint using the prepared core Levalloisian technique. These are generalized Mousterian assemblages with points, many side scrapers for hide preparation, knives, perforators, endscrapers, cutters, and other tools. Both caves also contain burials of adults and the immature, with adults receiving food offerings but the peripheral juveniles buried without grave goods.

The big difference between the two caves is the skeletons. The slightly older Tabun (ca. 40,000 years) yields Neanderthals of classical form, with large brains, protruding faces and brow ridges, and receding chins atop strong rugged skeletons.

Skhul, however, has the more evolved or modern-looking skeletons, with high foreheads, less prognathism, and some chin. The woman Skhul IX has a fairly delicate skeleton. These puzzling differences cause some paleoanthropologists to think that the two caves show the remains of two quite different populations. The Skhul remains would be left by people of more recent African affinity. The cultural similarity but biological disparity appears remarkable because usually cultural dissimilarities outweigh biological distances among human remains.

—Ralph Rowlett

of these early people. Findings include stone tools such as blades, bone tools, ornamentation, and forms of art approximately dated to 45,000 years ago. In Siberia in the site of Kara-Bom, approximately around the same period, stone implements have been found with human fossils indicating this as an early area for migration.

The gradual colonization of the warmer climes in Europe is believed to have followed that of colder climes. Having first established themselves in colder regions, evidence showed settlements in southwestern Europe followed. The sites of Willendorf in Austria and El Castillo in Spain are estimated to have been settled approximately 40,000 years ago, subsequently

following the settlement of more northerly latitudes fraught with colder weather and conditions. This is far different from previous hominid settlement patterns that only occupied the warmer regions of Europe, completely avoiding the northern climes. Anthropologists believe that human adaptation to this region occurred as a result of technological changes that necessitated adjusting to colder climates. Unlike the better-suited Neanderthals, modern humans would be heavily stressed by the climate of the north. Intriguingly enough, the fact that they chose to inhabit colder regions before moving to warmer regions illustrates the reliance on technology to adapt during their northern migrations.

It is believed by some anthropologists that the late migration of modern humans into western Europe is due to the heavy Neanderthal regional presence. It would follow that this is perhaps the reason they did not inhabit the warmer southern regions of Europe as well. As *Homo sapiens* emerged into Europe they sought to avoid regions inhabited by Neanderthals. It would be later when *Homo sapiens* would live in areas adjacent to Neanderthal settlements and compete for resources. Around 30,000 years ago there would hardly be any Neanderthals left and thus no reason not to inhabit adjacent regions, much less have them around to compete for resources.

There is debate among anthropologists about the fate of Neanderthals and whether the migration of modern humans has anything to do with their ultimate demise. Some scholars argue that modern humans interbred and gradually emerged as a sole species with a mixed genetic inheritance. A skeleton excavated in Lagar Velho in Portugal in 1998 displays some Neanderthal features along with modern human characteristics and is used as evidence of this position. Others argue that modern humans replaced Neanderthals in Europe and that there was no interbreeding among them whatsoever. However, the question of how the migration of modern humans led to the displacement and disappearance of Neanderthals remains unanswered.

The Last Glacial Maximum

Last Glacial Maximum (LGM, or Late Pleniglacial) is the term usually applied for the period of glaciation between 18,000 and 20,000 years ago. It was characterized by the lowest temperatures during the Pleistocene epoch and the maximal extent of the permafrost area.

At the time of the LGM the total area covered by glaciers exceeded the modern periods as much as three to four times, constituting about 30 percent of earth's total surface. In the Northern Hemisphere the ice sheet (the thickness of which reached up to approximately 1.8 miles) covered huge territories of North America, Greenland, Iceland, Scandinavia, and northern Eurasia. At the same time, some northern areas (Siberia, Manchuria, and some parts of Alaska) still showed no visible traces of glaciation due to prevailing westerly dry winds that considerably reduced precipitation and ice formation in these regions.

One of the most striking features of the LGM is the significant fall in average annual temperatures, up to 18 degrees Celsius (°C) lower than modern times. Paleoclimatic reconstructions made on the basis of data from a series of East European Late Paleolithic archaeological sites indicate that the LGM cold snap displayed itself unequally in different regions. In European Russia and the Ukraine, mean temperatures in January were 20°C to 29°C colder than today (with minimal meaning up to -35°C to -40°C); average temperatures in July were 5°C to 11°C lower than those today, and the maximum temperature in the summer never exceeded 20°C with probable light morning and night frosts. In contrast, in Siberia and Mongolia temperatures were only 7°C to 15°C colder in winter and 1°C to 7°C in summer. Light snow likely fell around the margins of the glaciers more than 280 days per year.

Temperatures dropped across the planet, even in places well away from the glaciers. In

very high and very low latitudes as well as in the tropics, climate became very arid. Annual precipitation averages declined 2.0–29.5 inches (50–750 millimeters). For example, average annual precipitation in Britain at that time is comparable to that in modern Morocco, and in southern Australia and the Sahel rainfall decreased up to 90 percent. In general, the annual precipitation rate across Eurasia during the LGM was about 9.8–11.8 inches (250–300 mm), thus creating vast deserts in both hemispheres.

The cold, dry continental climate typical of the Northern Hemisphere during the LGM was characterized by highly contrasted seasonal temperatures and in many areas led to the formation of large open grasslands when precipitation was sufficient. These grasslands supported many species of migratory herbivores that lived in large herds, such as mammoth, woolly rhinoceros, bison, horse, and reindeer. Dramatic and rapid climatic changes during the LGM sometimes created situations whereby certain species lost their favored niches and were forced to adapt to unfamiliar landscapes.

Plant and animal ecology were closely tied to latitude, with higher latitudes characterized by temperature extremes and low biomass. Close to the glaciers was a tundra environment characterized by extreme cold and low-growing plants. A mixed forest-steppe landscape with permafrost (ground frozen solid year-round) was found to the south of the tundra. Intensive erosion flattened the river valleys and upper areas of their watersheds in these areas. Adjacent to glacial sheet tundra landscape and situated to the south from them a belt of mixed tundra-forest-steppe landscapes correlated with a zone of permafrost distribution and were characterized by peculiar forms of flattened relief that originated due to intensive erosion in the river valleys and wash-out on the upper parts and watersheds. The trees that grew in this zone included pygmy birch and pine. Beyond the permafrost zone was the steppe, or grassland. Small patches of trees, mostly pine, birch, and alder, characterized these patches. In areas of low elevation, some patches of deciduous trees such as oak and elm were also found. The animal species that dominated the steppe environment included bison, horse, reindeer, and antelope.

The LGM was also marked by significant sea- and ocean-level decreases up to 328.1–426.5 feet (100–130 meters) below modern levels. Most inner seas such as the Black Sea functioned as continental fresh or brackish lakes, while smaller ones such as the Azov Sea did not exist at all. The Persian Gulf, the English Channel, and the Bering Strait were at this time dry land, thus creating land bridges that connected continents. Asia and North America were connected by the so-called Bering land bridge, thus enabling the colonization of the Americas by humans and animals from Siberia.

The most striking feature of the LGM is the dramatic deterioration of climate that significantly reduced the territories available for human use. The environment became patchy, and plant and animal biomass diminished considerably. In one sense, this was the first global environmental crisis experienced by humans. However, Late Paleolithic peoples were fully capable of adapting to these climate extremes.

The Retreat of the Glaciers and the Beginnings of the Holocene

The process of deglaciation and the transition to the modern geological era known as the Holocene begins with the process of glacial retreat and periglacial development dated to 17,500–10,300 years ago.

Gradual ice melting and ice sheet retreat to the north caused the transformation of landforms and associated tectonic processes. In Scandinavia it resulted in the gradual rise of the land (approximately 3.2 feet [1 meter] per 100 years); in North America it caused the origin of the peculiar terminal glacial moraines of Long Island, Nantucket, and Cape Cod. The North American Great Lakes and major lakes in Europe were created at this time as well.

Sea basin history provides insights into the final environments of the Pleistocene. One glacial melting resulted in the formation of the Baltic Sea in a depressed area. It began as a brackish estuary (Yoldian Sea) and was filled with saltwater, which arrived from the North Sea at the period of the opening of the strait between contemporary Sweden and Denmark. In the history of sea basins of southern areas of Eurasia, the final phase of Pleistocene was marked by significant sea-level rise (transgressions). Recent studies in this field provided by marine geologists have put forward a broad interdisciplinary discussion about catastrophic versus evolutionary consequences for human society of the sea-level rise in the Black Sea-Mediterranean corridor on the Pleistocene-Holocene border. One can observe significant growth of water levels of all major rivers of Eurasia as well as the development of small rivers and temporary estuaries and waterways.

This period is characterized by repeated climatic oscillations, which on a global scale were directed toward climate warming. Nevertheless, taken in a more narrow perspective, it is possible to detect a more complicated mode of climate evolution connected with alternations of warm phases with relatively cold periods during which ice sheets moved back to the south. These climatic changes happened unusually quickly for the Pleistocene. Climatic oscillations of the later phases of Pleistocene are displayed unevenly at different latitudes and caused the gradual and slow formation of zonal features of the landscapes.

The Lascaux interval traditionally is regarded as the earliest warm phase during the process of glacial retreat, dated to approximately 17,000 years ago. In western Europe it led to the development of deciduous forests that included elm, oak, hornbeam, alder, and nut-bearing trees, among others.

The first significant warming in what is now the boreal zone of Europe was detected in the northern region of Germany, where it was accompanied with the distribution of pine and birch forests in the interval of 15,000 to 13,000 years before the present. The first remarkable climate warming had caused the disappearance of relatively homogeneous periglacial landscapes

and their typical inhabitants such as mammoth, woolly rhinoceros, and musk ox.

The Older Dryas (or Dryas I) cold phase (not later than 14,500 years before the present) is usually correlated with restoration of periglacial arid steppe landscapes in the south and tundra-forest-steppe landscapes in the northern regions. The wide distribution of boreal vegetation is referred to as the Bolling interstadial (12,400–12,000 years before the present for western Europe and 12,800–12,000 years before the present in the East). In the northern part of Eurasia it was represented by birch and pine forests, with the gradual growth of spruce and deciduous species (oak and nut-bearing trees).

Following the Bolling interstadial, the Middle Dryas cold episode (12,200–11,800 years before the present) is marked by the disappearance of deciduous arboreal species and the further replacement of forest-steppe landscapes by dry grasslands.

The latest phase of the Pleistocene is referred to as the Allerød (11,800–11,000 years before the present), a warm and wet interval during which average temperatures of July could be as high as 13–14 degrees Celsius. This period was marked by wide distribution of boreal forests and forest-steppe landscapes with the presence of spruce and a low proportion of deciduous species over contemporary forest and forest-steppe in Eurasia. The northern periphery of the modern steppe zone was represented by mixed boreal forest-steppe landscapes gradually changing into meadow steppes to the south.

The Younger Dryas (or Dryas III) was the final climatic stage of the Ice Age and was marked by a slight and impermanent drop in temperature across Eurasia during the interval of 11,000–10,300 years before the present. It is traced by distribution of dry-adapted plant species in steppe landscapes and the appearance of arid steppes in the southern part of eastern Europe. In frames of forest-steppe and forest zones of Eurasia, birch and pine forest alternated with plots of dry-land plants. The presence of grasses and the low proportion of deciduous arboreal vegetation indicate that, taken in general, the Younger Dryas was the wettest interval among the cold phases of the final Pleistocene.

Homo sapiens in the New World

Evidence indicates that *Homo sapiens* first arrived in the New World during the Late Pleistocene era (11,000–126,000 years ago), although when and by what route remains a controversy. Historically, scholars thought that *Homo sapiens* first arrived in the New World no earlier than 11,500 years ago based on the distinctive style of lithic points found in 1933 near Clovis, New Mexico. According to the Clovis-First model, a small group of *Homo sapiens* hunters, possibly numbering under 100 individuals, entered the New World from Siberia at the end of the last Ice Age approximately 11,500–12,000 years ago. Prior to that, it was believed that most of Canada was covered by the Cordilleran ice sheet that was centered over the Rocky Mountains and the Laurentide ice sheet centered over the Hudson Bay, effectively blocking any way for *Homo sapiens* to enter North and South America. At the end of the last Ice Age, Clovis-First modelers hypothesized that *Homo sapiens* funneled through an ice-free corridor as a result of the melting of the two ice sheets. The Clovis-First model, despite its initial acceptance and popularity, has failed to stand up to the empirical evidence.

Four primary lines of evidence can be used in determining when *Homo sapiens* first arrived in the New World: biological, archaeological, linguistic, and cultural. Biological evidence consists primarily of dental and skeletal remains as well as genetic data, although in some rare cases trichological data (hair) has been used. Dental evidence indicates that *Homo sapiens* migrated into the New World from North Asia sometime around 20,000 years ago. Craniometric data, while not providing any chronological dates, indicates that the *Homo sapiens* that arrived in the New World at the end of the Late Pleistocene are not similar to any modern world popula-

tions. This has led scholars to conclude that either the crania of modern world populations has changed substantially enough that it no longer correlates with Late Pleistocene *Homo sapiens* crania from the New World or that the *Homo sapiens* populations that migrated into the New World were replaced by later migrations of more cranially modern humans. The genetic evidence, based on haplo group frequencies of genetic markers found on both the mitochondrial DNA (mtDNA) and the Y-chromosome, indicates that the first *Homo sapiens* reached the New World between 20,000 and 35,000 years ago from North Asia or Siberia.

The archaeological evidence, contrary to the biological evidence, does not contain any empirical evidence that would place *Homo sapiens* in the New World further back than 12,500 years ago—the date of the Monte Verde site located in Chile, South America—although a handful of controversial sites argue for an earlier date of arrival. The archaeological evidence indicates that *Homo sapiens* arrived in the New World between 11,000 and 13,000 years ago, peopling North and South America within this period. No conclusive evidence has been found that would indicate from where or by what means *Homo sapiens* made their way to the New World.

Two methods—multilateral word comparison and historical linguistics—have been established by linguists in an attempt to determine how old indigenous New World languages are and from where they may have derived. The method of multilateral word comparison was developed by James Greenberg in 1987 in an attempt to reduce all known indigenous languages into a tripartite division that could then be compared to other known language families. Greenberg used the method of multilateral word comparison to examine the rate of retention of a specific list of 200 words and concluded that slightly more than 80 percent of the list was retained over 1,000 years. Based on this method, he concluded that *Homo sapiens* migrated into the New World in three waves as demonstrated by his construction of three primary protolanguage families (Amerind, Na-Dene, and Aleut-Eskimo). He was unable to give a firm date as to when the first migration took place, but based on the method of multilateral word comparison,

THE KENNEWICK MAN CONTROVERSY

On July 29, 1996, a 9,300-year-old skeleton was found on the banks of the Columbia River in Washington state that came to be known as the Kennewick Man. After recovery, the Army Corps of Engineers announced its intention to repatriate the remains to four federally recognized American Indian tribes and a nonfederally recognized American Indian band under the Native American Graves Protection and Repatriation Act (NAGPRA). Subsequently, eight scientists filed suit to prevent repatriation, arguing that NAGPRA and the Archaeological Resources Protection Act (ARPA) gave them the right to study the remains. During June 19–20, 2001, Magistrate Jelderks heard oral arguments and on August 30, 2002, ruled in favor of the scientists. On February 4, 2004, the Ninth Circuit Appeals Court upheld Jelderks's decision. The Ninth Circuit agreed with Jelderks that Congress had used the phrase “that is indigenous” in its “common and everyday usage” and that a relationship must be shown with an existing tribe, people, or culture for the remains to be determined “Native American” under NAGPRA. This ruling has raised the question of whether the people who initially populated North America are biologically and culturally affiliated with contemporary American Indians.

Reconstruction of the Kennewick Man, giving a face to one of the oldest and most complete sets of human remains found in the United States. The 9,300-year-old remains discovered on the banks of the Columbia River near Kennewick, Washington, has triggered a property battle between scientists seeking the bones for research and native Americans wanting to give them a spiritual burial. (AP Photo/Perfect Image, James Chatters)

it is argued to have taken place at least 35,000 years ago.

The final line of evidence available for establishing when *Homo sapiens* first arrived in the New World stems from cultural or ethnographic evidence. Because of the ephemeral nature of cultural evidence, it is generally held by scientists not to be reliable beyond a few hundred years. However, oral traditions of contemporary American Indians and First Nations peoples hold cultural memories that can be traced back to the last Ice Age. Such oral traditions contain evidence of *Homo sapiens* experiencing the glacial melting of the Cordilleran and Laurentide ice

sheets but do not contain evidence of movements across or around these ice sheets.

Homo floresiensis

Homo floresiensis (nicknamed “the Hobbit”) is a species of the genus *Homo* found in 2003 in a cave on Flores, Indonesia. It is notable for its very small stature and brain size, its recent date, some anatomical features, and its association with stone tools and burnt animal bones. The existence of *H. floresiensis* shows that human evolution was one of multiple rather than single lineages until the very recent past.

Bones belonging to nine individuals have been excavated, but only one—a woman—is a near-complete individual. Based on bone measurements, *H. floresiensis* was about 3.3 feet (1 meter) tall with a brain size of about 380 cubic centimeters. The average modern human stature is 5.25 feet (1.6 meters) and the brain size of 1,300–1,800 cubic centimeters. The shape and thickness of the skull, the reduced size of the teeth, and the upright stance and stride show that it is within the genus *Homo*. The researchers’ interpretation, which has been accepted by most experts, is that it is a dwarfed descendant of early humans who reached Flores sometime within the last one million years. It is not an ape or directly descended from nonhuman ancestors. It is not a pygmy because pygmy brains are similar in size to those of other modern humans (*H. sapiens*). Other interpretations of its size, such as pituitary or microcephalic dwarfism, are not consistent with the skeletal features of *H. floresiensis*. Dwarfing is common among animal species isolated on small islands. On Flores itself a dwarf primitive elephant (Stegodon) is contemporary with *H. floresiensis*.

H. floresiensis existed until at least 14,000 years ago. The bones were found within a series of clay and silt layers beneath volcanic ash layers dated to 11,000–13,000 years ago by the luminescence dating technique. Two radiocarbon dates on charcoal associated with the skeleton and processed by the ABOX-SC method both

Homo floresiensis
(Hobbit)

H. floresiensis was a small-bodied and small-brained hominin known only so far from the Indonesian island of Flores that overlapped in time and space with modern humans, but may be dwarfed descendants of *H. erectus*. (Illustration by Jeff Dixon)

gave ages of about 18,000 years ago. These dates have been widely accepted.

The layers containing *H. floresiensis* also contained many stone tools and animal bones. The stone tools were mostly flakes and the cores from which these were struck, but there were also a few that had been subsequently shaped. The animal bones came from a wide range of species, including a Komodo dragon, a varanid lizard that grows up to 9.8 feet (3 meters) long, a rat, and a bat. Notably, 15 juvenile stegodons, which were broken up in ways suggesting that they were hunted and eaten, were present. *H. floresiensis* used fire, as demonstrated by a ring of burnt cobbles, but there are no signs of symbolic activities such as jewelry or the use of pigments.

The discovery of *H. floresiensis* was described by *Science* magazine as the most important scientific discovery of 2004 (when it was published). There are two aspects of wider significance in this discovery.

First, until this discovery human evolutionary history during the last 200,000 years was thought to be dominated by *H. sapiens* for the last 150,000–200,000 years. The Neanderthals of Europe were a recent offshoot of *H. sapiens* and died out about 30,000 years ago. While there is no agreement among experts, all agree that *H. floresiensis* is descended either from an earlier form of *Homo* or an australopithecine. Its existence demonstrates that modern human evolution continued the pattern of the last two million to three million years, with several coexisting species of humans. The presence on earth of only one species of humans is much more recent than previously thought.

Second, scientists have generally accepted that modern humans arrived in Australia at least 50,000 years ago, coming from Africa via Southeast Asia and Indonesia, and that these were the

first species to have made watercraft. However, Flores had been an island for millions of years, and thus the ancestors of *H. floresiensis* also must have had watercraft, demonstrating mastery of complex technology. This is forcing a rethink of current models of the evolution of technology.

■ Introduction: Holocene Environments, 10,000–4000 BCE

The Holocene is the name given to the most recent warm or interglacial period. It began in 10,000 BCE, when the major ice sheets that once covered much of Europe and North America were melting rapidly due to a rise in global temperature, a process that has continued into the present. The land at middle to high latitudes, which was depressed by the weight of the ice sheets, began to rebound, resulting in the formation of the Baltic Sea and Hudson Bay. Sea level was rising worldwide as the ice melted, and much of the continental shelf and the lower reaches of rivers were inundated. Carbon dioxide concentrations in the atmosphere were also rising and contributing to global warming. Land bridges were severed, creating islands around the edges of continents, notably in Southeast Asia and in the Mediterranean Basin. In high and middle latitudes, huge volumes of sand and gravel were deposited by streams issuing from the ice as melting occurred and moraines were dumped by the retreating margins of ice sheets and glaciers. Similar processes occurred in high-altitude regions, which were glaciated such as the Hima-

layas, Alps, and Andes. Many continental basins gouged out by highly erosive ice filled with water to produce some of the world's largest lakes, such as the Great Lakes of North America.

Such changing conditions greatly affected ecological processes and ecosystem characteristics. The global vegetation belts and their fauna that are evident today came into existence as individual plants and animals reacted to environmental change. Global warming and increased moisture availability encouraged soil-forming processes and the colonization by pioneer plants, such as mosses and lichens, of vast tracts of formerly glaciated or near-glacial land in the Northern Hemisphere. This began to create suitable conditions for the migration north of plants and animals. The great temperate and boreal forests came into existence as colonization proceeded through open woodlands and eventually closed forests. Extensive wetlands also developed at high latitudes, notably in Siberia and northern Canada where temperatures had become warm enough to allow plants to grow but not sufficiently warm to facilitate complete de-

composition. These forests and wetlands enhanced the carbon store within the world's vegetation and soils. Early Holocene forest establishment comprised the pioneer species of birch and pine, but within a few thousand years forests dominated by oak, elm, lime, poplar, alder, beech, and hornbeam had developed throughout temperate Europe. In the Mediterranean zone, herb and shrub associations gave way to evergreen oak and pine forests. In North America, following pioneer stages, temperate forests developed along the coastal regions and in the Great Lakes/St. Lawrence region. The latter were dominated by hardwoods such as oak, aspen, maple, and beech often mixed with softwoods such as pine, spruce, and fir. On the west coast conifers predominate, such as firs, pines, redwoods, and cedars with some hardwoods, such as cherry, oak, maple, and dogwood.

Lands not directly glaciated were also affected by climatic change but perhaps not quite so dramatically. In tropical forests, new species assemblages developed as tree species reacted to increasing temperatures and increasing precipitation. Many species migrated to higher altitudes, and forests expanded into savanna and grassland areas. Temperate and boreal forests in the Southern Hemisphere responded similarly, while the world's desert regions contracted as precipitation increased and caused grasslands and savannas to expand.

Although natural processes dominate the first half of the Holocene, it remains unique as an interglacial period because of the substantial impact of human communities on the environment, especially following the inception of agriculture, which occurred as the epoch opened. Deforestation, enhanced soil erosion, urbanization, and accelerated plant and animal extinction are all characteristic of the first half of the Holocene, especially in temperate Mediterranean and subtropical regions, but have since intensified considerably.

Postglacial Animal Extinctions Worldwide

Extinction—the dying out of a species—has been a natural aspect of life on earth since life first arose on this planet. At least five major extinction events are recognized from the fossil record: at the end of the Ordovician period (about 440 million years ago), at the end of the Devonian period (about 370 million years ago), at the end of the Permian period (the greatest of them all, about 245 million years ago), at the end of the Triassic period (about 210 million years ago), and at the end of the Cretaceous period (about 65 million years ago). There have been numerous smaller extinction events as well.

Another major extinction event is going on now: the Holocene event. It differs from other extinction events in the rate of species loss, which is much higher than at any other time in earth's history; thus, it is called the Sixth Extinction. While the first phase of the current extinction event began in the Pleistocene about 100,000 years ago as modern humans spread out of Africa, the latest phase began in spectacular fashion at the beginning of the Holocene with the disappearance of many members of the Pleistocene megafauna (large animals).

The best-known mammoth species is the woolly mammoth (*M. primigenius*), also called the Siberian or Northern mammoth, which probably emerged in Eurasia. About 50,000 years ago, during the height of the earth's last ice age, the woolly mammoth's range extended across northern Europe, Siberia, and much of North America. (Darryl Brooks)

The Cenozoic era, which began about 65 million years ago, has been dubbed the “Age of the Mammals” because of the diversification and dominance of mammal species throughout most of the world’s ecosystems. Mammals evolved to tremendous size during the ice ages, in part to help conserve heat (larger bodies retain heat better than smaller ones) but also because of a sort of arms race between predators and prey. Grasslands and savannas had expanded across the landscape.

While small size might be an advantage in forested environments where there are plenty of opportunities for concealment, it is not so effective in open environments where little cover was available. Thus, herbivores grew larger: the larger the prey, the more difficult they are to bring down. As herbivores grew larger, so did the predators that fed upon them.

Some of the most massive species in history of current mammal groups evolved during the Early Holocene (from about 11,000 to 4,000 years before the present). Those that went extinct include several species of elephant-like animals (mammoth and mastodons), ancient bison, the Irish elk, several horse species (in North America), ground sloths, giant beaver, saber-toothed cats, and dire wolves.

Mammals were not the only species affected. Birds (especially large bird species), reptiles, fish, and marine invertebrates have been noticeably affected by Holocene extinctions.

Considerable debate rages over the primary cause of the Holocene extinctions. Are they the result of natural processes driven by climate and environmental change? Or are they the result of the increasing human impact on the planet’s natural resources? Or do natural and human-driven processes together play a role?

One problem in teasing out the cause results from similar timing. In the Americas, the Clovis point—a major innovation in Stone Age hunting technology—appeared about the time that glaciers were receding. More than 70 percent of large mammal genera (groups of closely related species) disappeared from North and South America at about the same time. Many species show evidence of butchering of animals, based primarily on cut marks on bones, but clear evidence that hunters were the cause of death of

the animals is less common. Couple that with the coincidental change in climate, and the situation grows murkier.

The hypothesis that climate alone caused the extinctions has one major problem: climate has fluctuated quite a bit since the Late Pliocene, but most of the time there have been no corresponding mass extinctions.

Given that many species that survived since the Early Holocene were also hunted to a great extent, an “overkill” hypothesis does not seem sufficient. The spread of agriculture may have played a role in some areas, but since agriculture was limited to just a few regions until late in the Holocene, it cannot be blamed for the demise of most species in the Early Holocene.

Recent research has focused upon life history traits of Early Holocene mammals. Many species that went extinct had slow reproductive rates, regardless of body size. Many of the species that survived had higher reproductive rates, again regardless of body size. Some species with slower reproductive rates survived, but most of those lived in environments with plenty of cover available for concealment, or else their habitats were those too harsh to support large human populations. Many of the surviving species were nocturnal and/or tree dwellers. Thus, the life history model, while not indicating that overkill drove the Holocene extinctions, supports the hypothesis that hunting played much more of a role than climate.

Climate certainly played a role in influencing the characteristics and distributions of ecosystems on the planet. Plant assemblages, in particular, fluctuated in middle and high latitudes as glaciers advanced and receded throughout the Pleistocene and Holocene. There is no evidence for widespread extinction among plant species, however, as there is among terrestrial animal species. Likewise, there is relatively little evidence for an above-normal extinction rate among marine organisms.

Postglacial Environments in Europe and the Middle East

At the dawn of the Holocene, the environment of Europe and the Middle East went through drastic changes. The great ice sheets centered on what is now Scandinavia, the northern British Isles, and the Alps were shrinking.

Sea levels, which had been low enough to leave a broad land connection between the British Isles and western Europe, were rising, the waters filling in much of what is now the North Sea, the English Channel, and the Irish Sea. Anatolia (the thumblike peninsula of modern Turkey) was likewise broadly attached to southeastern Europe, but as the seas rose that link was likewise cut. The Baltic Sea, which at the beginning of the Holocene was a glacial lake, became connected with the ocean to form a brackish sea.

At the height of the last glaciation, Europe from the Alps north to the southern edges of the polar ice sheets was devoid of forests. A polar desert lay along the southern fringe of the ice sheets. Tundra covered the continent from the edge of the polar desert south to the Alps. Steppe—an arid or semiarid grassland or shrubland—dominated the Mediterranean region eastward through what is now Turkey and Iran and southward into the Middle East.

As the glaciers receded, the vegetation of Europe became more diverse. Tree species began to expand northward. While there is little evidence of trees in much of Europe during the last glacial maximum, those that began to recolonize Europe probably survived in natural refuges, either in areas that are now offshore (inundated by rising seas) or in protected areas, such as on

THE FORMATION OF THE ENGLISH CHANNEL, CIRCA 6500 BCE

The English Channel fills an ancient basin created by tectonic upheavals in the Mesozoic and Cenozoic. The channel itself—bound roughly by the Strait of Dover on the east and by a line running from the Isles of Scilly in Great Britain and Ushant in France to the west—was a broad lowland area connecting the British Isles to the European mainland at the end of the Devensian Glacial, the last great advance of glaciers in the British Isles.

At the height of the Devensian, sea levels were about 393.7 feet (120 meters) lower than today. The channel began to fill rapidly, however, about 10,000 years ago as the great ice sheets receded. In addition to the English Channel, Doggerland—a lowland area that now forms the floor of the North Sea—likewise began to fill. The flooding basins destroyed a number of human settlements as well as cut the land connection between the British Isles and continental Europe.

—David M. Lawrence

the southern slopes of the Alps, in the Balkans, or along the shores of the Black Sea.

Oak woodlands characteristic of the Mediterranean region were common in the uplands of the Levant (eastern Mediterranean). Steppe and desert were likewise common at lower elevations and throughout the Arabian Peninsula. The plants, particularly the grasses, and animals of the steppes and deserts laid the framework for domestication and the establishment of agricultural societies in the region.

Farther north at the crossroads of Europe and Asia in what is now Turkey, steppe vegetation was dominant throughout the region at the beginning of the Holocene. Forest and woodland vegetation became more abundant from Syria, throughout Anatolia, and into Greece and the Balkan Peninsula. Desert vegetation persisted in what is now northeastern Turkey, however. In most of the forested areas, conifers (pine and spruce) were replaced by broad-leaved species (basswood, oak, and hazel), although fir and beech became dominant in some parts of the Balkans.

Oak forests and woodlands dominated the Carpathian region of central Europe by the

middle of the Holocene (ca. 7,500 to 4,300 years ago). The relative abundance of ash, basswood, and hazel, all important components of the forests and woodlands, fluctuated over time. Farther west, birch, juniper, and pine woodlands gave way to a smorgasbord of deciduous species—including oaks, basswood, hazel, and others—by the Middle Holocene.

In the British Isles, tundra moved north as the ice retreated. The tundra vegetation was replaced by juniper woodland at the Pleistocene/Holocene boundary. Birch woodlands replaced juniper woodlands as the Holocene climate warmed. Hazel, pine, and willow followed birch. Alders, elms, oaks, and pines, which quickly gained a toehold in the southern portion of the British Isles, took longer—the Middle Holocene, about 6,000 years ago—to reach the northern part of what is now Scotland. Ash and basswood arrived in the south quite a bit later, about 7,000 years ago.

As glaciers retreated from the Baltic region, tundra, then pine and birch woodland, expanded throughout. Hazel, elm, and oak arrived by 9,000 years ago, followed by ash and basswood. Tundra was similarly replaced by pine woodland in central Scandinavia. In time, a belt of birch and alder developed at lower altitudes and latitudes. The altitudinal and latitudinal range of the pine and birch/alder belt shifted quite a bit as climate switched between warm and cold phases in the Holocene.

Toward the end of the Middle Holocene another environmental trend began, the clearing of forests and woodlands as agricultural settlements spread in the Middle East and southern Europe.

Postglacial Africa

Much of the African natural landscape looked quite different at the dawn of the Holocene at 11,000 years ago than it does today. Steppes, which are a type of grassland characteristic of arid areas, were much more widespread, while the ranges of ecosystems at opposite ends of the moisture continuum—deserts and humid tropical forests—were more restricted.

Steppe vegetation dominated northern Africa. Much of the Sahel, the region bordering the Sahara to the south, was likewise dominated by steppe, which extended farther north and west than today. At somewhat higher elevations, savannas—grasslands with scattered trees—became more prominent and were mixed with patches of forest. In central Africa, savanna prevailed at the lowest elevations, and evergreen forests prevailed at the highest. Compared to today, the elevation range occupied by both was greater, squeezing lowland tropical rain forest to a narrow band at middle altitudes.

Not surprisingly, tree lines were lower in the high mountains of East Africa. The drier climate favored xerophytic vegetation, plants adapted to dry (xeric) conditions, often with thick leathery leaves to limit water loss and thorns, spines, or other defenses to limit grazing. The xerophytic woods and scrub (characterized by stunted trees and shrubs) were mixed with steppe at lower elevations and graded into evergreen forest at higher elevations.

Steppe dominated much of southern Africa, with fynbos (a unique south African type of xerophytic woods and scrub) locally important. Much of Madagascar was covered by a patchwork of broad-leaved evergreen and mixed forest, with lowland tropical rain forest restricted to a much narrower elevation band than today.

The climate changes of the Early Holocene had far-reaching effects. The Holocene Thermal Maximum (from 11,000 to 5,000 years ago) was

➤ A WETTER SAHARA, CIRCA 6500 BCE

Mention of the Sahara Desert conjures up images of a vast sea of sand—waves of towering dunes constantly driven by the wind—broken up by rocky pavements and bare escarpments. What vegetation occurs is only in the vicinity of the relatively rare oases.

The Sahara was not always a place of such desolation. During the Holocene Thermal Maximum, rising sea-surface temperatures in the Atlantic strengthened thermal gradients, which in turn intensified the West African monsoon.

The intensified monsoon transported vast amounts of water over western and northern Africa. River systems were enlarged. Places such as Wadi Howar, now a dry canyon, were connected to the Nile by a river that ran through a landscape dotted with lakes, covered by steppe, savanna, and xerophytic forest and scrub. With this enhanced water supply, human settlements dotted areas where nothing but caravan trails survive today.

—David M. Lawrence

Satellite image reveals a previously unknown branch of an ancient river, buried under thousands of years of windblown sand in a region of the Sahara Desert in Libya. (NASA/JPL-Caltech)

characterized by warmer temperatures, changes in atmospheric and oceanic circulation, and changes in precipitation patterns. One of the more dramatic shifts in the Early Holocene was the African Humid period. Driven by a strengthening of the West African monsoon, the period was characterized by more rainfall in western and northern Africa. Much of what is now the Sahara was dotted with lakes as a result.

The wetter conditions led to widespread changes in the African landscape. In northwest Africa, mixed deciduous-evergreen forests dominated the uplands, while xerophytic woods and scrub were widespread at lower elevations. Farther east in what is now Egypt, steppe was widespread but mixed with xerophytic woods and scrub. The belt of forest and steppe ex-

tended south into the Sahara. In the Saharan uplands, mixed deciduous-evergreen forests could be found.

The belt of Sahelian vegetation—steppe to the north adjacent to the Sahara, with xerophytic woods and scrub and then tropical dry forest—encroached upon the Sahara from the south. The combination of encroachment from both the north and south greatly restricted the area occupied by the great Sahara itself.

While much of northern and western Africa was wetter, other parts of the continent were drier, central Africa in particular. The area of the lowland tropical rain forest in central Africa appears to have been reduced compared to today. Tropical seasonal forest was much more widespread instead.

Eastern and southern Africa were much the same as today, mixed deciduous-evergreen forests in the mountains, xerophytic woods and scrub in the plateaus, and fynbos in the Cape region of what is now South Africa. Tropical dry forest was widespread in what is now the southern part of the Democratic Republic of the Congo, and savanna was widespread in what is now northern Botswana. The major exception to the similarity to today is outside the Cape region of what is now South Africa: xerophytic woods and scrub rather than today's mixed deciduous-evergreen forest.

About 5,000 years ago the Holocene Thermal Maximum and the African Humid period came to a sudden halt. Climate cooled globally. The change in temperature patterns led to a weakening of the West African monsoon. As the monsoon weakened, the rains faltered in northern and western Africa. The desert reclaimed much of the Sahara and North Africa. The Sahelian vegetation belts shifted southward, and mixed evergreen-deciduous forests expanded in what is now South Africa.

Postglacial Asia and Australia

The continent of Asia was, as it is now, a land of vast contrasts at the time of the Last Glacial Maximum (LGM) in the Pleistocene 18,000 years ago. The ice sheets radiating out from Scandina-

via reached as far east as the Taymyr Peninsula in western Siberia. Lower sea levels—as much as 394 feet (120 meters) lower than today—exposed the wide land bridge of Beringia, between Asia and North America, as well as another, Sundaland, that helped bridge the gap between Southeast Asia and Australia.

As would be expected, ecosystems characteristic of cold climates, such as tundra and boreal forest (taiga), were more widespread than today. Tundra extended southward below 60°N throughout much of Siberia. Steppe, rather than boreal forest (taiga) as in today, extended southward from the tundra belt. The boreal forest, the dominant biome of northern Eurasia today, was greatly reduced, as was the desert belt of central Asia.

Ecosystems characteristic of warmer climates, such as deciduous and tropical forests, were displaced toward the equator. Wet-dry tropical forest and savanna covered much of mainland Southeast Asia. Sundaland consisted of an extensive savanna corridor. Tropical rain forests, widespread through the islands that make up Southeast Asia today, were, as temperate forests, greatly limited in extent; tropical forests did not reach northward to the latitudes of southern China as they do today.

Mainland Australia and surrounding islands were much drier, such that deciduous forests occurred at sites now occupied by tropical rain forests and arid woodlands, and shrublands and grasslands were more widespread in the south and center of the continent. On New Guinea alpine tree lines were likewise lower, reflecting the cooler temperatures. Boreal forest (to the north) and mixed conifer forest covered the main islands of Japan.

Temperatures warmed rapidly and stayed warmer as the LGM ended and worldwide deglaciation accelerated through the end of the Pleistocene and into the Holocene. As a result the great northern ice sheets receded, and Alpine glaciers throughout the continent likewise shrank.

Climate patterns of the glacial era changed to patterns more like those of today. Wetter conditions accompanied the warming temperatures. As climate patterns changed, so did ecosystem distributions, with tropical and temperate ecosystems expanding northward (and upward) at

the expense of polar (and alpine) ecosystems. Superimposed on the general trend toward warmer, wetter conditions, however, was variability in the extent and distribution of the South Asian and East Asian monsoons. When the monsoons extended their reach, ecosystems that depend on mesic (wetter) conditions spread. When the monsoons were reduced in extent, arid-zone ecosystems spread.

With rising sea levels, the low-lying regions of Sundaland and Beringia were inundated, converting the former into a vast archipelago between Asia and Australia and the latter into an oceanic barrier between Asia and North America. The changes affected the dispersal of plants and animals between the landmasses, with major effects on global and regional biogeographic patterns.

One of the most drastic transformations in Asia occurred in the northernmost latitudes. The widespread tundra ecosystem began to change from a landscape dominated by herbaceous species to one dominated by shrubs. A nascent boreal forest began to spread across the northern landscape, eventually forming a buffer zone between the tundra to the north and steppe mixed-conifer forest and deciduous forest to the south. Mixed-conifer forest and deciduous forest expanded northward, and desertlike conditions began to spread from central Asia into China. Deciduous forests extended southward as well, encroaching into areas such as the Black Sea basin formerly dominated by steppe.

By the middle of the Holocene some 6,000 years ago, forest belts on the Asian mainland had shifted: mixed-conifer and deciduous forest displaced boreal forest to the north as well as displaced steppe and desert to the west (the westward expansion was made possible by a stronger monsoon); montane deciduous and coniferous forests displaced alpine tundra in upland areas. Broad-leaved evergreen forest spread northward well into eastern China as well as upward in upland areas, in each case occupying regions now covered by deciduous forest. Tropical rainforest likewise expanded northward into southern China.

Ecosystem distribution throughout Southeast Asia was largely similar to that of today, with tropical rainforests in the islands giving

THE DISAPPEARANCE OF SUNDALAND

Sundaland is a region of islands and shallow seas that extends from Southeast Asia eastward to the edge of the Asian continental shelf, in particular to the Mindoro Strait between Palawan and the rest of the Philippines; the Makassar Strait, which lies between Borneo and Sulawesi; and the Lombok Strait, between Bali and Lombok.

During the Pleistocene, when sea levels were as much as 394 feet (120 meters) lower than today, much of Sundaland was above sea level: a vast coastal plain punctuated by highlands. As a result, Asian land animals spread throughout the region. The deep-water barrier between Sundaland and the islands to the east prevented Asian land animals from spreading eastward but also prevented Australian land animals from spreading westward.

As the Pleistocene came to an end sea levels rose rapidly, reaching about 197 feet (60 meters) below present sea level at the Pleistocene/Holocene boundary about 12,000 years ago, then to just above modern levels about 6,000 years ago. As the waters rose, what had once been the edge of a vast continent was transformed into part of the largest archipelago in the world.

—David M. Lawrence

way to tropical seasonal forests to the north, in Indochina, and to the south near Australia. Ecosystems in Australia were likewise similar to that of today, although arid woodlands and shrublands were more common in some portions of southern Australia, while mesic forests were more common in the eastern part of the continent. In the mountains of New Guinea and Sumatra, tree lines were higher than today, indicating warmer conditions than at present. All vegetation zones correspondingly shifted upward. In Japan, ecosystems were distributed much as they are today.

Beringia and the Peopling of the New World

Beringia stretches from the Kolyma River and the Kamchatka River in Russia eastward through Alaska to the Mackenzie River in Canada. During the last glaciation when sea levels were as much as 394 feet (120 meters) lower than today, continental shelf areas in the Arctic Ocean and Bering Sea were dry, greatly adding to the size of this already vast region.

Ice sheets were not ubiquitous features of the Ice Age landscape. Eastern Siberia was largely ice-free with the exception of alpine gla-

ciers at high elevations. Much of Alaska and northwestern Canada were likewise ice-free, the lack of ice largely being a function of low precipitation rather than high temperatures.

The massive Laurentide ice sheet lay to the east of the region (beyond the Mackenzie River), and the Cordilleran ice sheet lay to the south (from the Alaska Range east across the southern portion of the Yukon Territory to the Mackenzie Mountains). The uneven distribution of ice provided broad corridors for human colonization of the Americas from Asia.

During the last glacial maximum, about 18,000 years ago, tundra dominated the Beringian landscape. The dominant plant species of the tundra varied from region to region, ranging from herbaceous species in some locations to shrubs and heath in others. Many animal species roamed Beringia's plains and included woolly mammoth, American mastodon, woodland and tundra musk ox, western camel, Lambe's horse, steppe bison, elk, caribou, Dall's sheep, short-faced and grizzly bear, American lion, saber-tooth cat, wolf, and wolverine. Some animals migrated from North America to Asia; others migrated from Asia to North America. One species in particular, humans, moved across Beringia from Asia to find an entire hemisphere awaiting colonization.

While few scientists dispute that the ancestors of Native Americans came from Asia via Beringia, considerable controversy has raged over what path the migrants took. The standard hypothesis—the Clovis-First hypothesis—is that the ancestors of the Native Americans followed game from Siberia eastward into Beringia, spreading into Alaska and the Yukon, and then migrated along a gap between the Laurentide and Cordilleran ice sheets up the Mackenzie River Valley into southern Canada and the United States.

The hypothesis was advanced to explain the finds of Clovis artifacts, especially the distinctive Clovis point, near Clovis, New Mexico. The artifacts date to about 13,000 years before present; the ice-free corridor was believed to have opened up shortly before that. One of the strongest pieces of evidence for the Clovis-First hypothesis was the apparent lack of evidence of

This fresco at the National Anthropological Museum of Mexico depicts hunters migrating from Asia across the Bering Strait. North, Central, and South America were populated over a period of thousands of years after nomadic hunters crossed over a land bridge into North America about 35,000–9,000 BCE. (The Art Archive/National Anthropological Museum Mexico/Dagli Orti)

human habitation in the Americas prior to the appearance of Clovis culture.

The Clovis-First hypothesis did have problems, though. For one, the apparently rapid spread of human settlement to sites as far south as northern South America demanded an alternative migration route, a coastal route as opposed to an inland route. As more research was done on potentially ancient settlement sites, evidence accumulated to support the notion that Clovis culture could not be the first. The evidence is diverse, consisting of both archaeological and genetic data.

Sites in the Siberian portion of Beringia indicate that the ancestral populations of Native Americans had established themselves in the Arctic by 32,000 years before present. While there is evidence of bone artifacts apparently worked by humans as far east as the Yukon about 28,000 years ago, the earliest undisputed evidence of human habitation in North America comes from Swan Point, Alaska, and dates to about 14,000 years ago. The materials found at Swan Point are similar to items found at sites in eastern Siberia. A number of sites sprang up in eastern and western Beringia in the ensuing centuries.

For the human colonists to spread south, corridors had to open through the barriers formed by the ice sheets. A coastal route appears to have opened up by 15,000 years ago, while the route through the Mackenzie Valley did not open until at least 14,000 years ago. Evidence that humans used boats to make their way along the coast comes from a 13,000-year-old site on Santa Rosa Island off the California coast. The controversial Monte Verde site in Chile, which dates to 14,600 years ago, should spell the death knell of the Clovis-First hypothesis.

Genetic evidence supports a pre-Clovis colonization of the Americas. A recent analysis of Native American mitochondrial DNA (mtDNA) suggests a single founding population. That population went through a bottleneck—a drastic reduction in population size, possibly caused by a small group splitting off from a larger group—during the Last Glacial Maximum about 20,000 years ago. By 18,000 years ago, however, the population was expanding. Y-chromosome data also indicates a single founding population—

from the same region in Asia—that crossed into North America at the same time.

As the Holocene began, the great ice sheets were retreating throughout the region. Sea levels were rising, flooding coastal areas and cutting Beringia in two to form the Bering Strait between Asia and North America. By then, however, the Native Americans had established a beachhead and were on their way to transforming the American landscape.

Postglacial North America

The North American landscape underwent a radical transformation as the last of the Pleistocene ice sheets receded. At the Last Glacial Maximum (about 18,000 years ago), two large ice sheets dominated the continent. The Laurentide ice sheet radiated out from northern Canada, reaching the location of the Ohio and Missouri rivers to the south, the Mackenzie River to the west, and the sea ice of Davis Strait to the east. The Cordilleran ice sheet covered much of the northwest of the continent, from Alaska and southern Yukon south to what is now the Snake River and Columbia River valleys.

The two ice sheets met along the continental divide, isolating Beringia to the northwest from the rest of the continent. To the south, the Cordilleran ice sheet likewise fused with the Pine-dale ice sheet radiating out from the central Rocky Mountains. Aside from helping create some of the continent's major river valleys, the glaciers bulldozed much of the landscape of the north, pushing ahead debris later left behind

THE DISAPPEARANCE OF THE CONTINENTAL SHELF

North America's continental shelves—the apron of gently sloping land that tilts from the coast to the ocean depths—were once part of the continent's coastal plains. During the Last Glacial Maximum (about 18,000 years ago), sea levels were much lower, about 394 feet (120 meters) lower than today.

In the Arctic, the Laurentide ice sheet was largely contiguous with the Arctic ice pack and Greenland ice sheet, but a broad belt of land was exposed along the Atlantic and Gulf of Mexico coasts. A much narrower belt was exposed along the Pacific.

As the glaciers melted, sea levels rose, and what was once coastal plain became continental shelf. Islands, such as Newfoundland in the Atlantic and Vancouver in the Pacific, formed as they were cut off from the mainland by rising waters. Valleys, such as the Chesapeake, Delaware, and San Francisco, flooded to become bays or fjords. The lower reaches of river valleys were transformed into submarine canyons, such as the Hudson River Canyon—an underwater extension of the Hudson River valley in New York.

—David M. Lawrence

as the deposits that make up Long Island, Nantucket, and Cape Cod.

In the west, the ice dammed up immense volumes of water to create massive glacial lakes such as Missoula in western Montana, Agassiz in the Great Plains of Canada and the United States, Lahontan in northwestern Nevada, and Bonneville in the Great Basin.

Lower sea levels (as much as 394 feet [120 meters] lower than today) exposed vast areas that now make up the continental shelves off the Atlantic, Gulf of Mexico, and Caribbean coasts and lesser areas along the Pacific coast and the Gulf of California. Newfoundland and the Grand Banks were connected to the North American mainland.

As with other portions of the Northern Hemisphere, ecosystems were compressed to the south. Polar tundra and polar desert occupied the southern fringes of the ice. Boreal forest (taiga) and cool mixed forests covered the eastern United States, with the exception of pine woodlands that were widespread in Florida and

along the Gulf Coast. Steppe and mixed woodlands dominated the Great Plains.

The topographic diversity of the Southwest makes generalizations difficult, but it was more or less a mix of alpine tundra at high elevations, subalpine forest and woodland at lower elevations, and pinyon-juniper-oak woodland in a mosaic with steppe and desert at lower elevations. Cool conifer forest covered the higher elevations of the Pacific coast, with steppe, desert, and woodlands at lower elevations.

Pinyon-juniper-oak woodland and steppe were common at lower elevations in northern and central Mexico. Conifer forests dominated the higher elevations. A savanna belt ran across southern Mexico into the Yucatan Peninsula, continuing eastward into the Greater Antilles. The tropical rain forest belt was restricted to the southern portion of Central America.

The retreat of the ice sheets was accompanied by significant changes in atmospheric circulation, weather, and ecosystems. The changes were most heavily felt in the southwestern and northern regions. Drying conditions led to expanding deserts and retreating forests in the Southwest and expanding grasslands on the Great Plains. Tundra retreated northward with the ice, giving way to boreal and mixed-conifer forest.

Rising temperatures and melting ice eroded the ice dams holding back the great glacial lakes. The dams periodically burst, leading to some of the greatest flash floods in earth's history. A series of such floods, draining Glacial Lake Missoula, burst down the Columbia Plateau toward the Pacific, creating the Channeled Scablands of eastern Washington state. Glacial Lake Agassiz burst in virtually every compass direction before its final cataclysmic flood into the Hudson Bay. As a result of the floods and the drying of the climate, many of the lakes shrank or disappeared altogether. Lake Winnipeg is the largest remnant of Glacial Lake Agassiz. The Great Salt Lake is the largest remnant of Lake Bonneville.

While many of the glacial lakes shrank, basins in areas once covered by ice filled with water. The Great Lakes were formed by meltwater from the Laurentide ice sheet as well as by drainage from Glacial Lake Agassiz.

The massive amounts of water from the shrinking ice sheets ultimately filled the ocean basins, raising sea levels and flooding areas that now form the continental shelves. The rising seas split Beringia, cutting North America off from Asia. Higher sea levels separated Newfoundland from the mainland and submerged the Grand Banks.

By the middle of the Holocene (about 6,000 years ago) temperatures had warmed significantly. Drier conditions spread as well, especially throughout the West. Ecosystems had shifted their ranges northward and in montane regions, upward toward higher elevations, so that their distributions were quite similar to ecosystem distributions today.

Tundra covered much of far northern Canada and Alaska. Boreal forest occupied a broad belt from the Bering Strait to the eastern shores of Newfoundland. Cool mixed forest spread across southeastern Canada and the northeastern United States, and deciduous forest, with occasional mixed conifer forest, covered the southeastern United States. The mixed woodlands that had been a major presence on the Great Plains had given way to steppe and prairie.

Desert (in the south) and steppe (in the north) had spread throughout low-elevation areas of the West and northern Mexico. As elevation increased, pinyon-juniper woodland gave way to pine woodland, subalpine forest, and alpine tundra. Cool conifer forest covered a greater portion of the highlands of the Pacific coast, again with a mix of desert, steppe, and woodland at lower elevations.

The northward extension of forest bands coupled with the expansion of deserts created a much more complex patchwork of ecosystems in Central America and especially Mexico. Deserts encroached upon woodland and steppe ecosystems. Savanna ecosystems took up a smaller portion of central Mexico, as tropical rainforests spread into southern Mexico. Tropical rainforests likewise displaced savanna in the Greater Antilles.

Postglacial South America

The continent of South America largely escaped the effects of Pleistocene glaciation. The mountainous spine of the continent, the Andes, was heavily glaciated, as were parts of the southern landmass of Patagonia including Tierra del Fuego, the archipelago at the continent's southernmost tip.

During the Last Glacial Maximum, about 18,000 years ago, tundra and cold steppe were present along the fringes of the ice. Steppe dominated the southern portion of the thin strip of coast along the Pacific Ocean. In the rain shadow of the Andes, desert spread across the nonglaciated plains of Patagonia. Cold desert gave way to semidesert in a thin strip of northern Argentina and Uruguay from the Andes to the Atlantic Ocean.

To the north, in the Altiplano (high plains) of the central Andes, tundra, alpine desert, and alpine semidesert prevailed. Desert dominated in the tropical latitudes along the Pacific coast until giving way to tropical savanna in the northwestern portion of the continent and tropical rain forest near the Isthmus of Panama.

In the lowlands east of the Altiplano—in eastern Bolivia, northern Argentina, and Paraguay—lay a small expanse of desert ringed by a larger area of semidesert. Much of southern and eastern Brazil was covered by grassland with the exception of a small patch of forest in the south-central part and tropical semidesert in the far east of the country.

North of the grasslands lay a wide belt of tropical savanna surrounding a large expanse of tropical rain forest in the upper reaches of the Amazon Basin and a smaller belt of rain forest in the Guianas. To the north of the savanna, in the Orinoco River basin, lay a belt of desert

THE RISE AND FALL OF LAKE TITICACA

Lake Titicaca is a large lake in the northern Altiplano (high plain) of the Andes along the Bolivia-Peru border. At 12,500 feet (3,810 meters) in elevation and more than 3,400 square miles (8,800 square kilometers) in area, it is the highest navigable lake in the world. It is also the largest lake in South America.

Early in the Quaternary, a vast lake, Mataro, occupied the northern and central Altiplano. Mataro's shoreline was more than 450 feet (137 meters) higher than today. Mataro eventually dried and then reappeared as Lake Cabana (1 million years ago; 300 feet [91 meters] higher). Cabana likewise dried and was replaced by a series of smaller lakes in the northern Altiplano: Ballivian (600,000 years ago; 165 feet [50 meters] higher), Minchin (30,000 years ago; 50 feet [15 meters] higher), and Tauca (13,000 years ago; 15 feet [5 meters] higher).

From the Early to the Middle Holocene (approximately 6,000 to 3,000 years ago), the levels of Lake Titicaca dropped as much as 330 feet (100

Lake Titicaca, on the borders of present-day Bolivia and Peru. (Totorean/Dreamstime)

meters) below current levels. At the end of that period, the waters rose rapidly and reached the current level about 2,100 years ago.

—David M. Lawrence

surrounded by a thin ribbon of semidesert. In the highlands of Colombia, conifer and mixed forest and grassland-shrub ecosystems were common.

Deglaciation of South America began in three stages beginning at about 17,500 years before the present and ending at 11,500 years ago. Precipitation patterns began their adjustment to more modern conditions about 1,600 years after temperatures began to rise. Glaciers, in general, began to retreat into higher elevations, although there was a short glacial advance in the area of the Strait of Magellan.

In Tierra del Fuego and southern Patagonia west of the Andes, tundra gave way to steppe and eventually forest. East of the Andes, the cold desert that had covered much of central and southern Patagonia had been replaced by semidesert. Steppe covered much of northern Argentina.

Throughout the Andes, tundra and alpine desert occurred at higher elevations along the fringes of alpine glaciers as well as at the highest elevational limits that vegetation could grow. Montane steppe spread through the Altiplano. In

the southern part of South America's Pacific coast, temperate forest and woodland and scrub replaced the coastal desert, which still occupied a sizable swath of the coastal area in the southern tropics. To the north, in northern Peru, the coastal desert gave way to semidesert, which in turn gave way to tropical rain forest in southern Ecuador.

East of the Andes, tropical ecosystems spread to cover most of the continent. Tropical savanna covered a broad band of inland territory from northern Argentina to central Brazil. Monsoon forest dominated much of eastern Brazil, with temperate evergreen forest in Uruguay and the extreme southern coast of Brazil. A sizable band of tropical rain forest grew along the southeastern coast. The tropical semidesert in the far eastern portion of the country gave way to thorn scrub and scrub woodland.

The range of tropical rain forest greatly expanded to cover virtually all of the Amazon River basin and extended into southern portions of the Orinoco Basin. Tropical montane forest

occupied Andean slopes along the edges of the Amazon Basin. In the Guianas, tropical savanna had been replaced by cloud forest—a type of cool rainforest—at the Pleistocene-Holocene transition, but drying climate in the Holocene created a patchwork of rain forest and savanna.

Tropical savanna replaced the belt of desert and semidesert north of the Orinoco. In Colombia, grassland-shrub ecosystems gave way to cool mixed forest. At lower altitudes, tropical seasonal forest replaced cool mixed forest; seasonal forest was in turn replaced by tropical dry forest and steppe at lower elevations, although tropical rain forest was also widespread.

■ Introduction: The Lifeways of Our Earliest Ancestors—The Miocene to Neanderthals

The evolution of the hominids, that is, great apes plus modern humans (*Homo sapiens*) and their humanlike ancestors, began in the geological era known as the Cenozoic, which began 65 million years ago. The later part of this era, the Neogene period beginning 22 million years ago, is divided into four epochs: the Miocene (23.03 million to 5.33 million years ago), the Pliocene (5.3 million to 1.806 million years ago), the Pleistocene (1.8 million to 10,000 years ago), and the Holocene (10,000 years ago to the present). By the time it opened, a wide range of mammals characterized the Neogene fauna, which included numerous species of apes. Much diversification subsequently occurred and produced a species from which humans and great apes (gorillas and chimpanzees) emerged. From which species and precisely when this occurred has not been established, though opinion focuses on circa 5.5 million years ago based on fossil evidence from East Africa plus molecular evidence. A key genus is *Australopithecus* and especially the species *Australopithecus afarensis* (known as Lucy), which emerged circa four million years ago, because it is considered to be the missing link, or one of several, between the quadripedal apes

and the upright or bipedal *Homo* species. The details of subsequent evolutionary links are equally controversial, although all later species are recognized as members of the genus *Homo*. The earliest species include *H. erectus*, *H. rudolfensis*, *H. ergaster*, *H. heidelbergensis*, and *H. habilis*, the ancestors of *H. neanderthalensis* and *H. sapiens*. Each of these species contributed to the technological base that distinguishes humans from other animals and played a key role in their lifeways. However, information on when and how various technologies, such as tool making and the domestication of fire, emerged is sparse due to limited fossil finds.

The Miocene apes, the oldest being the genus *Proconsul*, emerged in tropical forests in Africa. They then spread via the Arabian Peninsula into Asia and Europe, where they diversified as humid forests expanded due to climatic warming in the Middle Miocene. They were similar anatomically to modern apes, and most could exploit canopy resources as well as those on the ground. All were herbivores, with some being specialist fruit eaters (frugivores), and others were leaf eaters (folivores); some had thicker tooth enamel, which broadened their food base to include nuts. Genera include *Dryopithecus*

and *Sivapithecus*, which prevailed in Europe and Asia, respectively. The genus (species) that is ancestral to modern apes, including gorillas and chimpanzees, the closest relatives of humans, and humans themselves probably migrated into Africa from Eurasia in response to climatic cooling and drying that reduced forest extent and favored savanna. Opinion differs as to which genus this was, but *Dryopithecus* or its relative *Ouranopithecus* from Greece are the most likely. The ability to exploit open rather than forested habitats may have been a crucial factor in the evolutionary process that eventually gave rise to genus *Homo*, possibly in East Africa. Another debated issue concerns the timing of the split between the great apes and the australopithecines, the ancestors of modern humans, that is attributed to the Late Miocene and Early Pliocene (7.5 million to 4.5 million years ago).

The australopithecine subfamily is also controversial insofar as some researchers consider that it comprises only four genera, while others believe that it comprises six genera: *Sabelanthropus*, *Orrorin*, *Ardipithecus*, *Australopithecus*, *Paranthropus*, and *Kenyanthropus*. These genera existed between circa seven million and two million years ago. Their fossil remains have been found only in Africa, notably East and South Africa, with the fossils of one genus, *Sabelanthropus*, found in Chad in north-central Africa in 2001 and 2002. The genera *Sabelanthropus* and *Orrorin* comprise just one species; the former is the oldest, dated to circa seven million years ago, with *Orrorin*, found in the Tugen Hills of Kenya in 2000, being the next oldest at six million years ago. Given the paucity of remains, remarks about the respective lifeways of these species must remain conjectural. For example, in relation to bipedalism, uncertainties surround *Sabelanthropus*, but *Orrorin* walked upright but had climbing abilities; both lived on fruit and vegetable matter, though the latter may also have been a meat eater. *Orrorin* inhabited a dry evergreen forest rather than savanna or grassland; this questions the origin of bipedalism, which, as stated above, is usually associated with savanna environments. The *Ardipithecus* genus, which existed between circa 5.8 million and 4.4 million years ago, contains two species: *A. kadabba*, the older species, and *A. ramidus*.

Fossils of both species have been found in the Afar Depression in the Awash region of Ethiopia and are distinguished on the basis of dentition. Both were bipedal, and although plant remains from their sedimentary context indicate woodland and grassland in a floodplain environment, it cannot be ascertained if either *Ardipithecus* species were specific to one of these habitats or were more versatile exploiters of all habitat types. The *Australopithecus* genus comprises five species: *A. anamensis*, *A. afarensis*, *A. africanus*, *A. babrelgazhali*, and *A. garhi*, in order of age. Fossils of the first of these, dated to circa four million years ago, are limited to three sites in East Africa near Lake Turkana and one site in the Middle Awash region of Ethiopia. The species has tooth enamel that is thicker than *Ardipithecus* and larger molars that indicate a larger proportion of coarse food types in its diet. It may have been able to climb trees in common with its predecessors. *A. afarensis* is a particularly well-known species given publicity surrounding the discovery of the 40 percent skeletal remains known as Lucy in Ethiopia's Middle Awash region in 1974 and the attribution of preserved footprints at Laetoli, Tanzania, to the species.

Further finds have been uncovered in Ethiopia. The species is dated to circa 3.5 million to 3.8 million years ago and has characteristics that are apelike and humanlike, that is, small brain size, curved fingers, and a pelvic structure that indicates bipedalism. This suggests that bipedalism preceded brain enlargement, which occurred in later hominids. *A. afarensis* is considered to be a direct ancestor of the *Homo* genus and hence of modern humans. This was not, however, a meat-eating species. *A. africanus* fossils, dated to between three million and two million years old, are found at Taung, Makapansgat, Gladysvale, and Sterkfontein in South Africa, the Taung Child being the most famous. This bipedal species has a larger brain size than *A. afarensis* and other anatomical features that are more humanlike, though it retains curved fingers. It may have been the direct ancestor of the genus *Paranthropus* that existed at the same time as early species of *Homo*. *A. babrelgazhali*, found in Chad, and *A. garhi*, found in Awash, Ethiopia, existed circa 3.5 million to 2.5 million years ago; both are represented by relatively few fossils,

and both are probably members of lateral branches of hominin evolution. It is possible that *A. garhi* was the first hominid species to produce stone tools, given the presence of crude tools in associated sediments from Ethiopia.

Homo habilis (the name referring to skill), the first species of *Homo*, emerged circa 2.5 million years ago in East Africa and died out circa 1.5 million years ago. It is questionable as to which australopithecine species was the immediate ancestor of *H. habilis* though it may have been *A. ramidus* and there is debate about the place of *H. habilis* as an ancestor of *H. sapiens*. It is also possible that *H. habilis*, *H. rudolfensis*, and *H. ergaster* were contemporaneous.

Fossil finds are predominantly from the Rift Valley of East Africa in association with flake tools known as the Olduvan industry. These tools were associated with opportunist scavenging of animal carcasses, which reflects a shift in food procurement strategy from predominantly vegetarian to omnivore. Moreover, *H. habilis* was itself a hunted species, notably by big cats. *H. ergaster*, considered by some paleoanthropologists to be *H. erectus*, lived between 1.8 million and 1.4 million years ago, had a larger brain than *H. habilis*, and reached a height of circa 5.2–6.2 feet (1.6–1.9 meters). It is associated with a new type of stone tool industry known as the Acheulian, which contains a range of artifacts used for a variety of purposes such as meat and wood cutting. *H. erectus*, so-named to reflect its upright status, emerged circa two million years ago in Africa with a larger brain size than its ancestors. It was the first hominid to migrate out of Africa to Asia and Europe, used the sophisticated Acheulian tool kit, and was a hunter-gatherer rather than a scavenger. The species may have lived in small groups, though it had no more than a primitive language and had the ability to start and control fire. It persisted longer than most of the ancestors of modern humans, though much depends on the classification of so-called *erectus*-grade fossils; some argue that the Asian fossils reflect true *H. erectus* and that European and African fossils are different species of *Homo*. There is also debate as to whether *H. ergaster* or *H. erectus* gave rise to the later *Homo* species such as *H. antecessor*, *H. heidelbergensis*, *H. neanderthalensis*, and *H. flores-*

siensis. All were hunter-gatherers, used fire, were organized in groups, made stone tools, and were thus able to manipulate their environment and resources to some degree. *H. antecessor*, the remains found at Gran Dolina in northern Spain, lived between 1.2 million and 800,000 years ago and probably practiced cannibalism. At Boxgrove in southern England, the remains of *H. heidelbergensis*, circa 500,000 years old, are associated by butchered bones of rhinoceros, horse, and red deer. This species may be the direct ancestor of *H. neanderthalensis*, which lived between 350,000 and 30,000 years ago. Both had a primitive language. *H. neanderthalensis* lived at the same time as *H. sapiens* in Europe and Asia and had a similar brain size. They were active hunters and are associated with several stone tool assemblages. Important features of Neanderthal culture include the burial of the dead and care for the infirm.

Diets of Our Miocene and Early Pliocene Ancestors

The Superfamily Hominoidea, which includes all living and fossil apes and humans, is a group of anthropoids who have a lower molar with a shared Y-5 cusp and fissure pattern. The earliest fossil with this molar pattern is *Aegyptopithecus* from the Fayum in Egypt, which lived during the Oligocene epoch around 30 million years ago. In the Early Miocene epoch, from 25 million to 16 million years ago, there were many different kinds of these apes. Their fossil remains come from a series of sites near Lake Victoria in East Africa. While they have the Y-5 lower molar pattern, they were quadrupeds like *Aegyptopithecus*, with monkeylike bodies. Around 16 million to 17 million years ago, a land bridge was created between Africa and Eurasia roughly where the Middle East is today. Soon afterward, hominoids are found throughout Asia

► DETERMINING EARLY HUMAN DIET— AN ALTERNATIVE APPROACH

Anatomy remains the traditional way of determining early human adaptation and diet, but stable carbon isotopes offer a new perspective. Isotopes are chemical elements with different atomic weights. Carbon has three isotopes: ^{12}C , ^{13}C , and ^{14}C . The first two are stable isotopes; the third, ^{14}C , is unstable or radioactive and provides the basis for radiocarbon dating.

The ratio of ^{12}C and ^{13}C is used to reconstruct diet or past environments. It reflects the way that plants discriminate ^{13}C during photosynthesis. The ratio is lower in C3 plants (trees, bushes, shrubs, and forbs) than in C4 plants (mainly grasses). Values change as one goes up the food chain from plants to herbivores to carnivores. Julia Lee-Thorp and her colleagues studied carbon isotope ratios in bones and teeth of *Australopithecus africanus* and *Paranthropus robustus*. While there were some dietary differences, both were making use of C4 resources. But these could have been things like tubers or even termites.

Isotopic analysis of soil carbonates can help determine what the vegetation patterns were like in key stages of human evolution. East African vegetation is supposed to shift from forest to grassland starting in the Middle Miocene, but this happened at different times in different places.

Lee-Thorp, J. A., M. Sponheimer, and N. J. Van der Merwe. "What Do Stable Isotopes Tell Us about Hominid Dietary and Ecological Niches in the Pliocene?" *International Journal of Osteoarchaeology* 13 (2003): 104–113.

and Africa. By the Late Miocene (eight million to five million years ago), most were extinct or reduced in distribution. But in Africa, the Late Miocene is associated with the appearance of the first possible human ancestors. Referred to as hominids (Family Hominidae) or hominins (Tribe Hominini), they share skeletal adaptations for upright walking using two legs, or bipedalism. Possible hominids from the Late Miocene include *Ardipithecus* from the Middle Awash in Ethiopia, *Sabelanthropus* from Chad,

and *Orrorin tugenensis* from central Kenya. But little is known about the posture and movement of any of these forms. Postcranial or body bones are poorly known, so we are not sure if any of these forms were bipedal.

In the Pliocene epoch, from 5 million to 1.8 million years ago, the first australopithecines appeared in East and southern Africa. The best known of these is *Australopithecus afarensis* from the Hadar area of Ethiopia, which lived between four million and three million years ago. It shows a combination of ape and human traits. While clearly adapted for bipedalism (walking on two legs) on the ground, the retention of long arms and curved digits in both the hands and feet argue for some degree of living in the trees. In terms of the brain, face, and teeth, *Australopithecus afarensis* was extremely apelike. Other forms include *Australopithecus africanus*, a species that lived between 2.5 million and 3 million years ago in South Africa, and the later robust forms usually put in the genus *Paranthropus*. *Paranthropus* appears around the same time as the earliest members of our own genus, *Homo*.

The majority of early ape and human fossils are jaws and teeth. Their morphology can be studied for features that might help us determine diet. These include jaw size and strength, tooth size, tooth enamel thickness, and pitting, wear, and other marks on the teeth. All early humans except for *Ardipithecus* exhibit thick tooth enamel, suggesting that they were eating hard, brittle foods. *Ardipithecus* has the thin enamel that one sees today in chimpanzees, animals that prefer to eat fruits.

One of the classic debates about reconstructing early human diet involves *Paranthropus* (or *Australopithecus*) *robustus* (South Africa) and *Paranthropus* (or *Australopithecus*) *boisei* (East Africa), two species that lived between 2.6 million and 1 million years ago. They are differentiated from the earlier or "gracile" australopithecines (*Australopithecus africanus*) by their enlarged back teeth (premolars and molars) and changes to the face and jaws, which are adaptations for enlarged chewing muscles. Anatomists suggested that *Paranthropus* ate hard, compact foods that caused a lot of tooth damage, while *Australopithecus africanus*, like early *Homo*, had a more generalized diet.

Recent studies of dental microwear have argued differently. Modern primates that eat hard and tough foods have pitted teeth with complex damage patterns, but not *Paranthropus boisei*. It resembles other Pliocene hominids. Another study suggested that *Australopithecus africanus* ate tough foods, while the diet of *Paranthropus robustus* included more brittle items. But both had a varied overlapping diet. Our own genus, *Homo*, appeared around 2.5 million years ago and lived side by side with *Paranthropus*. Members of *Homo* have always been argued to have such a generalized diet, with increasing use of meat over time. The enlarged brain of *Homo* had to be fueled by meat protein. It is not a coincidence that early *Homo* fossils are associated with the first flaked stone tools; these were probably used to butcher animals for meat. But most archaeologists argue that intentional hunting of animals for food only began with *Homo erectus* or *Homo ergaster* around 1.8 million years ago. This enabled *Homo erectus* to spread out of Africa into Asia.

Olduwan Times Lifeways

The appearance of stone tools in Africa around 2.5 million years ago marks the beginning of the Olduwan Industrial Complex. The oldest stone tools come from Gona, Ethiopia, and although they are not directly connected with hominid fossils, it is assumed that early *Homo* created the assemblage. Later sites, such as Olduvai Gorge and Koobi Fora, confirm hominin involvement. The manufacture and use of stone tools was an extremely significant factor in the lifeways of *Homo habilis* (and *Homo rudolfensis*).

Collection of Olduwan tools discovered at Olduvai Gorge, Tanzania, dating to about 1.8 million years ago. (The Natural History Museum, London/The Image Works)

Olduwan artifacts were simple tools created by knapping (hitting) a rock in order to remove stone flakes. The rock from which the flakes were removed is called the core. Both the core and the flake could be used as tools. A chopper is defined as a core tool from which flakes were removed from one face of an end of a cobblestone (creating a unifacial chopper) or from both faces of the same end (bifacial chopper). Pebble tools are also core tools but had more extensive knapping that often covered the entire surface of the stone. Flake tools, on the other hand, were made on the chips of stone removed from the core. They could have been used as such or further modified through detailed knapping along the edge(s). Choppers, pebble tools, and worked flakes are commonly found in Lower Paleolithic sites. The sharp edges of the all-purpose Olduwan tools may have been used to prepare plant or animal food.

Vegetal foods make up 60–80 percent of the diet of most modern hunting and gathering groups, so it is likely that this was also the case for the early hominins. Since plant remains rarely survive in the archaeological record, however, the types of plants consumed and their importance cannot be assessed. Evidence of meat consumption consists of scattered stone artifacts together with fragments of animal bone, some of which were cut with sharp flake tools or broken to remove the caloric-rich marrow. Such

assemblages were found at Hadar, Olduvai Gorge, and Koobi Fora. Distinguishing butchered bones from natural animal death assemblages is difficult, however. Taphonomic processes, including trampling, root growth, soil movement, and carnivore activity, can create similar-looking bone breaks, cut marks, and spatial patterns.

How the hominins acquired meat remains unclear, although most scholars suggest that scavenging took place. Hunting prey requires skill and communication, which may not have been advanced enough between 2.5 million and 1.7 million years ago. Incipient human cognitive and communicational abilities are implied, however, by the tendency of right-handedness tool manufacture. Fifty-seven percent of the Koobi Fora flakes were created by right-handed knappers, while a modern chimpanzee assemblage would contain tools more or less equally divided between left- and right-handers. The lateralization of the brain and marked functional separation of the cerebral hemispheres of modern humans may have already begun.

Other cultural aspects of Olduwan lifeways remain elusive. The early hominins may have carried their multipurpose Olduwan tools from site to site, which differentiates them from the expedient chimpanzee tool users, but site alteration, food sharing, a division of labor between sexes, and other expressions of social behavior cannot be distinguished. Simple shelters and living floors, representing a seasonally occupied home base, were identified at Olduvai Gorge by Mary Leakey in 1971, but a reinvestigation of these features suggested that tree roots, not hominin construction, were responsible for their creation. Moreover, there is no confirmed proof of shelter construction until 300,000 years ago at Terra Amata, France. There is, however, some evidence to suggest the caching of tools at sites, which does imply a plan to return to a specific place. Moreover, concentrations of archaeological remains found at a number of Olduwan sites may reflect the accumulation of garbage (discarded animal bones, tools, and waste flakes from tool manufacture), which is a distinctively human trait. Unfortunately, confirming that these artifact concentrations were made by hominins rather than by natural processes is dif-

ficult. Therefore, determining whether *Homo habilis* was using a home base, a lifestyle similar to modern hunting and gathering groups, is uncertain.

Evidence for the early use of fire is also ambiguous, as charcoal has little chance of survival at Olduwan sites. Concentrations of burned bone at Swartkrans in South Africa, reddened patches of sediment at Koobi Fora in northern Kenya, and burned clay at Chesowanja in central Kenya may be the result of campfires, but these features can be created by brushfires as well. Direct archaeological evidence for the oldest confirmed use of fire comes from Locality 1 at Zhoukoudian, China, where thick ash deposits, ash lenses, burned stones and bones, and charcoal pieces date to about 600,000 years ago. This site, however, postdates the Olduwan period by at least one million years.

Little of the Olduwan lifeways is known for certain, but it is clear that this was a period of significant change. The evolution of the first *Homo* species and the initial use of stone tools were likely the result of adaptations to a changing environment between three million and two million years ago. The shrinking of the forests due to the cooling and aridification of Africa meant spending increasing amounts of time on the expanding grasslands. The nearly upright bipedal posture, increased cranial capacity, and flexibility at the shoulder, arms, and hands allowed the hominins to compete in this environment. Tools helped them access new food resources, including meat and marrow, that diversified their diet and allowed for adaptive success over other hominids.

Although the fossil evidence is still limited for the Olduwan period, tool manufacture and butchering activities added an archaeological component to the record, thereby increasing our ability to study this stage of hominin development. Examining the early *Homo* fossils together with the archaeological remains reveals that although *Homo habilis* and *Homo rudolfensis* were not yet human, they may have exhibited early humanlike behavior. As more sites are discovered, our understanding of the Olduwan lifeways will hopefully become clearer.

The Lifeways of *Homo erectus*

Homo erectus was a highly mobile species and was the first hominin species that left Africa and explored Eurasia. *Homo erectus* made simple tools out of stone, of which the most advanced is the hand ax. They employed a scavenging behavior, but the sophistication of their hunting skill can be questioned. Studies of the larynx, which houses the vocal apparatus, indicate that *Homo erectus* could not produce complex sounds. Most likely, *Homo erectus* language was simple in construction and restricted in its range of expressions. The larger brain might be related to a more complex lifeway. There is some controversial evidence of the controlled use of fire, but consensus is emerging that *H. erectus* did control it. The successful dispersal over Africa and into Eurasia can be attributed to an efficient way of walking with a striding gait combined with the availability of suitable habitats at that time and not to advanced tool technology and related cognitive abilities.

Stone tools made by *Homo erectus* are simple and include choppers, scrapers, points, and hand axes, often of a large size. Some tools show retouch and edge modification, indicating that

HUNTERS OR SCAVENGERS—THE ROLE OF MEAT IN THE DIET OF EARLY *HOMO*

Most scholars now agree that meat made up part of the diet of *Homo habilis* and *Homo rudolfensis*. Just how significant meat was to early *Homo* and how it was acquired remain unclear, however. Assuming that these hominins consumed a similar diet to modern hunter-gatherer groups, 60–80 percent of their food would have consisted of vegetal produce and 20–40 percent of meat and marrow. Evidence of meat consumption exists as concentrations of fragmented animal bones with stone tools at sites such as Olduvai Gorge and Koobi Fora. Several of the bones were cut with sharp stone flake tools or broken with Olduvai choppers to remove the meat and caloric-rich marrow. Distinguishing butchered bones from a natural bone assemblage is difficult, though, as taphonomic processes (fossilized), including trampling and carnivore activity, can create similar-looking fracture patterns and cut marks.

The acquisition of meat was likely through scavenging because hunting animals requires skill and communication, attributes that may not have been advanced enough at that time. There are several cases where the cut marks are overtop tooth marks on the bones, revealing that early *Homo* butchered the animals after carnivores had fed on them. There are, however, bones with tooth marks overtop cut marks, implying the opposite order of consumption, but most of these bones were from older animals that may have died of natural causes. Even if early *Homo* were scavengers, they would have needed to be fairly efficient in order to reach and butcher the animal before other carnivores arrived.

—Shawn Bubel

they were used more than once. The earliest stone tools attributed to *Homo erectus* consist of simple core choppers and rough flake scrapers and were made some 1.8 million years ago at Omo and Turkana in East Africa. The technique is considered a continuation of the Olduvai technology. Around 1.2 million years ago, a change took place in the shape of the stone tools made by early *Homo erectus*. The first hand axes and cleavers (bifaces) appear. The stone was now

➤ DIET AT ZHOUKOUDIAN

Although Zhoukoudian Locality 1 is one of the oldest archaeological sites for which there is abundant data about diet, the interpretation of this evidence remains controversial. Part of the evidence comes from the first excavations when field methods were rudimentary, and even for the more recently examined material, a tendency persists toward a global interpretation instead of a stratum-by-stratum reconstruction. Despite ambiguities, some conclusions seem irrefutable.

Both meat and some plant foods were eaten, although it is unclear as to the proportions of each. Since the site features were intermittently inhabited by other large predators, it is unclear just what meat the hominids ate. It must have been mostly wide-antlered deer, *Euryceros pachyosteus*, since the majority of bones, largely fractured and some burnt, belonged to this species. Since the main cave adjoins a natural trap, it was relatively easy to kill injured animals with wooden clubs and spears, used even by modern chimpanzees. Other apparent food game includes smaller deer species and seemingly mollusks. The rare bones of humans were subjected to the same treatment as accorded game animals.

Hackberries were clearly consumed, either raw or ground up for cooking into dry cakes on the ubiquitous rounded river pebbles heated by the fires. Both animal and plant foods were at least sometimes cooked by the omnivore *Homo erectus*.

—Ralph M. Rowlett

worked on both sides and symmetrically. This technique is called Acheulean. A famous group of sites is Olorgesailie in southern Kenya, dated to around 0.9 million years ago. Hand axes of the Acheulean type are typically oval and teardrop-shaped. Outside Africa, the first cobble or chopping tools appear in China around 800,000 years ago at Yunxian and Lantian, coinciding with the first firm evidence of *Homo erectus* in China.

The earliest evidence of tool making in Asia comes from Longgupo, dated to 1.8 million years ago. Its hominid remains are attributed to an early *Homo*, yet they are still under debate. There is, though, no doubt so far about the nature of the artifacts. They are primitive and crude

stone tools. The site itself was not a living floor but instead is better interpreted as a hyena den. *Homo erectus* often visited carnivore dens, possibly to collect bones, antlers, and horns for making tools or for other purposes. Primitive tools were also discovered at Dmanisi in the Republic of Georgia, in association with *Homo erectus* fossils (also named *Homo georgicus*), possibly dated to 1.8 million–0.9 million years ago.

At Zhoukoudian in China, no less than 100,000 stone tools and flakes were excavated, ranging in age from 400,000 to 250,000 years ago and possibly older. The cave itself was not likely used as a living place for *Homo erectus*. Instead, the cave was primarily used by hyenas or bears. *Homo erectus* came there regularly to get some fleshy remains and marrow, as evidenced by cut marks on some bones made by quartz flakes. Carnivore gnawing and bite marks sometimes overlay the cut marks. Also, *Homo erectus* itself fell prey to the large carnivores. Typically in the past damaged human skulls were thought to be proof of cannibalism but are now explained as hyena activities. Zhoukoudian is only one of the many sites with combined activity of large carnivores and *Homo erectus* scavenging behavior.

Whether *Homo erectus* knew how to kindle and keep a fire or not is not fully resolved. In Africa, some sites are seen as evidence for deliberate and controlled use of fire by *Homo erectus*, such as Swartkrans in South Africa and Chesowanja in Kenya, dating to about 1.5 million years ago. In China the evidence comes from Zhoukoudian, where several ash layers were found. The ash is piled up on the limestone floor of the cave up to 19.6 feet (6 meters), indicating that *Homo erectus* used the cave for many years and kept a fire. This knowledge of fire was challenged in the mid-1980s by Lewis Binford and colleagues, who argue that the ash was not produced by controlled fire in a hearth.

No evidence whatsoever has been found for symbolic behaviors among *Homo erectus*. So far no symbolic objects were unearthed. Purposeful burials are unknown. Carnivore dens that were frequented by *Homo erectus* also, as a rule, contain bones and skulls of *Homo erectus* itself, which ended up there as a result of animal scavenging.

Neanderthal Lifeways—Hunting, Gathering, and Scavenging

Most of the stone tools found at Neanderthal sites belong to the Mousterian Industry of the Middle Paleolithic period (250,000–40,000 years ago). It is important to note, however, that Mousterian tools were also made by early *Homo sapiens*. It is therefore necessary to distinguish the assemblages created by the Neanderthals living in Europe and western Asia from the others. Moreover, the Châtelperronian Industry is linked with the latest Neanderthals that lived alongside *Homo sapiens* populations in Europe. These artifacts provide insight into Neanderthal lifeways just before they became extinct.

Mousterian tools were made of flakes and blades knapped from stone cores. They commonly include scrapers, projectile points, and denticulates. Mousterian artifacts were typically created from prepared stone cores, meaning that rock nodules were first shaped in order to knap off particular flakes that were further modified into tools. Mousterian core preparation likely extended from the careful shaping of Acheulean hand axes during the Lower Paleolithic period. Specifically, the Levallois technique of core preparation involved removing a number of waste flakes in a systematic way to create the desired core shape. With the core prepared, a predetermined sized and shaped flake was struck. These flakes were typically long and had a sharp cutting edge. Based on microwear analysis, it is now clear that some of these flakes were used as such, but many were further shaped into tools. This modification was achieved by pressure flaking, also called retouching, the edge of a flake blank.

Selection of flint tools, Mousterian, 50,000–35,000 BCE. (Musée des Antiquités Nationales, St. Germain-en-Laye, France/The Bridgeman Art Library)

The location and shape of the retouch are used to define the tool. A double convex sidescraper, for example, was retouched on both edges of the flake, and these modified edges were rounded outward from the midline of the tool. A point is defined as a flake on which two continuously retouched edges converged at the tip, while denticulates were retouched to produce a serrated edge. This classification system, which remains in use today, was introduced by François Bordes to formalize a Mousterian typology.

Although the names of the tools imply a particular function, this is not necessarily the case. Advances in residue and microwear analysis revealed that only the denticulates were used in just one way, that being shaving or whittling wood. Scrapers were used to cut and scrape wood, flesh, bone, hide, and soft plant material. Points were also used mostly on wood, but polishes and striations on the base of some suggest that they were fastened (hafted) to wooden

➤ EARLY CANNIBALISM IN ANCIENT EUROPE

An anthropological controversy surrounds the issue of whether Neanderthals practiced cannibalism. Artifacts that show tooth marks and considerably brutal treatment of Neanderthal corpses provide substantial evidence that cannibalism was practiced among groups of Neanderthals. However, Neanderthals also are well known for burying their dead, and this leads some anthropologists to contend that perhaps their treatment of corpses illustrates a ritualistic preparation previous to burial.

Professor Gorganovič-Kramberger from Croatia discovered various scattered bones in a Neanderthal excavation at Krapina in the province of Zagreb that offered evidence that the bones had been split. It was speculated that this was proof of extraction of marrow for consumption, that is, that cannibalism had taken place among this particular group of Neanderthals. In other findings there was substantial evidence that Neanderthal skulls have been opened to extract the brain, and some have been found to be displayed, perhaps as trophies. In

addition, tooth marks found on bones from animals consumed by Neanderthals have also been found on bones from human corpses. The combination of all these findings is suggestive that Neanderthals perhaps practiced some form of cannibalism.

Other anthropologists, however, contend that these examples are not proof of cannibalism among Neanderthals but instead are evidence of ritualistic practices in regard to burial and commemorating the dead. At this point the evidence remains ambiguous.

handles. With the exception of a few points from Kebara and Qafzeh in Israel, there is little evidence to suggest that points were hafted to wooden spears and thrown.

The Mousterian Industry as a whole is remarkably uniform throughout the Middle Paleolithic period and between sites. The slight differences in the Neanderthal tool assemblages may well be connected to the available raw stone material, where sizable nodules of high-quality flint resulted in larger and better-formed tools. Various economic uses of the artifacts could have created different assemblages as well, although this is the least likely explanation since many of the scrapers served as multipurpose tools. Tools in different stages of use may also account for assemblage variability because resharpening modifies the shape of the artifact. With this in mind, assemblages with smaller heavily retouched artifacts reveal intensified tool use.

Much of the evidence used to understand how the Neanderthals adapted to their environment comes from the area around Les Eyzies, France, where more than 200 Middle Paleolithic sites have been found. Most of these sites are in

caves or rock shelters, which offer excellent archaeological preservation conditions. The environment supplied an abundant source of water and raw materials with which to manufacture stone tools. Shelter could be found in the rock cliffs, although open-air sites were used as well. The reindeer living in the area provided a large amount of the protein in the Neanderthals' diet. An analysis of the age of the butchered reindeer remains showed that this region was occupied year-round.

The Neanderthals are thought to have been big game hunters and followed large herds of animals across the open grasslands and tundra. Faunal remains from various sites substantiated the consumption of reindeer, red deer, fallow deer, bison, wild oxen, wild sheep and goats, gazelles, and horses. Bones from elephants (mammoths) and rhinoceroses have also been found albeit in much smaller quantities. How these animals were acquired is more difficult to assess. As mentioned above, very few hunting weapons have been found, and the strategies that the Neanderthals would have used were rarely preserved. Moreover, scavenging cannot be ruled

out, as several campsites contain only limb elements that may have been taken from the kills of other predators or natural deaths. What does seem clear is that *Homo neanderthalensis* took advantage of the animal populations present at the time. Environmental reconstructions across time and space revealed fluctuations in certain animal species, which was often matched by the faunal assemblages created by the Neanderthals.

Other cultural evidence revealing the lifeways of the Neanderthals includes the burial pits that were reported from La Chapelle-aux-Saints, La Ferrassie, and Le Roc de Marsal in France; Kebara Cave in Israel; and Shanidar Cave in Iraq. Neanderthals were likely buried at many other sites as well, as this is the only plausible explanation for the nearly complete skeletons that were found. The burials were relatively simple, however, and lacked grave goods of any sort. Neanderthal bones from Crombe-Grenal and the Abri Moula in France were cut and burned, so the idea of cannibalism must also be considered. This could also explain the large number of extremely fragmented remains of at least 20 individuals from Hortus Cave in France and 14 or more from Krapina Cave in Croatia. Alternatively, sites such as these may have been affected by postdepositional processes such as rockfalls, which could have fractured the bones, and the cut marks may reflect the de-fleshing of the bodies before burial rather than cannibalistic activities.

No matter how culturally adapted the Neanderthals were to their environment, they quickly disappeared when *Homo sapiens* moved into Eurasia. For a brief period of time around 40,000 years ago, the two populations lived in close proximity to one another. Neanderthals living in western Europe may have been influenced by the newcomers, as is evidenced by the Châtelperronian Industry. Tools from this industry resembled Mousterian artifacts but also included well-made endscrapers and burins as well as formal bone artifacts and pierced animal teeth, all of which are characteristic of *Homo sapiens*' Upper Paleolithic assemblages. Eventually, however, the behaviorally inferior Neanderthals were outcompeted for resources and vanished from the archaeological record.

■ Introduction: The Lifeways of Early Modern Humans to circa 10,000 BCE

Modern humans, *Homo sapiens*, evolved in Africa between 250,000 and 150,000 years ago. Early species are often referred to as archaic *Homo sapiens*. There are two subspecies: *Homo sapiens idaltu*, meaning elder wise human, which is now extinct, and *H. sapiens sapiens*, the subspecies to which all human beings alive today belong. There is dispute about which hominid species was the immediate ancestor of *H. sapiens* and about the relationship with Neanderthals (*H. neanderthalensis*).

Both species may have evolved from *H. heidelbergensis*, which in turn evolved from *H. ergaster*, or the relationships might be more complex, with *H. ergaster* giving rise to *H. antecessor*, the common ancestor of *H. heidelbergensis* and *H. rhodesiensis*, which were the precursors of *H. neanderthalensis* and *H. sapiens*, respectively. Modern humans are bipedal and have a large brain (a volume of more than 1,350 cubic centimeters), well-developed language skills, and complex social networks. Unlike many of their

Illustration of a group of Neanderthals sitting around a fire holding lance-like weapons, 30,000 BCE. (Time Life Pictures/Getty Images)

ancestors, they exert a substantial direct and indirect influence over their environment and have the capacity to plan and to express memories, ideas, etc., in words and/or pictures and make music.

Modern humans evolved during a geologically turbulent time in the earth's history, notably the formation and subsequent melting of major ice sheets as global climate cooled for circa 100,000 years, warmed for circa 20,000 years, and cooled again for a further 100,000 years until circa 12,000 years ago. Such change may have stimulated the evolutionary process, or it might underpin the reasons that resulted in modern humans following in the footsteps of *H. erectus* out of Africa and into Europe and Asia and being more adventurous as it entered Australasia and eventually the Americas. Many questions surround the timing of such migration, whether or not there was more than one major migration, and whether there was any interbreeding with ancestral populations of *H. erectus* in Europe and Asia. Moreover, molecular evidence is difficult to interpret; it confirms the importance of an African origin but does not clarify other issues. Dated fossil evidence indicates that a significant migration out of Africa occurred circa 100,000 years ago, with modern humans colonizing Asia by 60,000 years ago and reaching Australasia circa 50,000 years ago and Europe by 35,000 years ago. A little later *H. neanderthalensis* became extinct, but why this

occurred and what, if any, role was played by modern humans is open to question. The issue of colonization of the Americas is particularly controversial, with conventional views focusing on 20,000 to 15,000 years ago and a route involving northeast Asia and a land bridge over the Bering Strait. However, evidence of human presence from several sites in South America indicates an earlier arrival circa 35,000 years ago.

The ancestors of modern humans had begun the practice of tool making from wood, stone, and bone and had learned to domesticate fire and to hunt as well as to recognize useful plant food sources. Modern humans developed these technologies and initiated new ones. In terms of archaeology, modern humans emerged during the Middle Paleolithic circa 300,000 to 45,000 years ago, while numerous sites, particularly in Asia and Europe, attest to major cultural developments during the Upper Paleolithic circa 45,000 to 10,000 years ago. Many fossil hominid remains from Africa and Europe dating from between 300,000 to 150,000 years ago are difficult to ascribe to a given species, as they have features common to Neanderthals, modern humans, and even *H. erectus*. Thus, detail relating to where and when *H. sapiens* first emerged is elusive. This period seems to have been one of transformation. Examples of important but later African sites with the remains of *H. sapiens* include the Klasies River Cave in South Africa, with remains dated to between 120,000 and 70,000 years ago; the Omo I sediments of Ethiopia, from which a partial skeleton is dated at circa 130,000 years ago; and sediments at Herto, Ethiopia, with several crania dated to 160,000 to 154,000 years ago. Of special importance is the Qafzeh site in modern-day Israel; this is a rock shelter where several skeletons of *H. sapiens* have been discovered and dated to circa 100,000 years. The bones were stained with red ochre, probably as part of a burial ritual. Nearby, the Skhul Cave also contains the remains of *H. sapiens*, while the Tabun and Kebara caves have yielded Neanderthal remains and Mousterian tools. This opens up the question of links and/or interactions between the two species, though their occupation of these sites may have been at different times. There is a paucity of evidence for the colonization of East Asia by *H. sapiens*

until circa 40,000 years ago; possible examples include fossils from Ngandong in Java and Jinniushan in China. The former is at most 53,000 years old, and the latter could be 200,000 years old; however, attribution of fossils to *H. sapiens* and dating are disputed. In Europe more sites have been investigated but are not without controversies. For example, in Petralona Cave near Thessalonika, Greece, a skeleton with mixed species traits and disputed dating (400,000–300,000 years old) was found in 1959, and in Sima de los Huesos at Atapuerca, northern Spain, many hominid remains circa 300,000 years old have been excavated that have archaic *H. sapiens* as well as Neanderthal characteristics.

Many anthropologists believe that major changes in human behavior and the capacity for innovation occurred around 60,000 years ago and may have been associated with a migration surge into Eurasia. This date gives credibility to the emergence of distinct cultural practices that are evident from widely distributed archaeological sites. There was a shift from open camps to covered sites, notably caves and rock shelters, many of which have yielded information on tool industries, hunted animals, wildlife, and art. Stone tool assemblages provide insight into the abilities and activities of early modern humans. Many Middle Paleolithic sites in Africa and Europe contain stone tools, referred to as Mousterian after the type site at Le Moustier in the Dordogne region of France. This “industry,” which predominated between 200,000 and 40,000 years ago and comprises flakes, scrapers, and points produced by working a flint core, is associated with Neanderthals in Europe, but in Africa and the Near East modern humans also produced it. Several other industries, all named after type sites in France, characterize the Upper Paleolithic sites of different cultures, first emerging circa 40,000 years ago separately in both Asia and Africa. This was the Aurignacian period, circa 40,000 to 28,000 years ago, that is associated with both *H. sapiens* and *H. neanderthalensis* in Europe and parts of Africa. It was followed by the closely related Châtelperronian, circa 40,000 to 34,000 years ago, and comprised stone and ivory tools, including characteristic denticulate (toothed) tools; it is predominant at sites with remains of *H. neanderthalensis*. The Gravettian, 28,000 to 22,000 years

ago, postdates Neanderthals and includes bone and ivory tools and ornaments such as Venus figurines; small pointed blades were used as spear tips to hunt a range of animals. The Solutrean period, circa 22,000 to 19,000 years ago, followed with a range of stone, bone, and antler tools with very sharp edges being made by pressure flaking and the heating or cooling of flint stones to shatter them in controlled ways. The last Upper Paleolithic period is the Magdalenian, circa 18,000 to 12,000 years ago, that is dominated by delicate flaked stones for arrows, scrapers, hooks, and spears; multibarbed harpoon points; and spear throwers made of wood, bone, or antler. Portable art (e.g., carved antler and ivory for decoration and figurines) was also evident, and microliths were becoming increasingly important. Tool kits enabled hunting and gathering, encouraged specialization within groups as they became increasingly sophisticated, and promoted communal activity as well as division of labor.

Art featured in the lifeways of early modern humans but not their predecessors. Figurines, cave paintings, decorated or carved ivory, and petroglyphs attest to the development of the capacity to represent aspects of their environment and the appreciation of beauty. Such items may also be linked to religion and thus to abstract thinking, while they also provide information on lifeways such as hunting. The increasing sophistication of tools and the depiction of hunted animals in cave art, the oldest of which are those of Chauvet in the Ardeche region of France at circa 32,000 years old, emphasize the importance of hunting. The most widely depicted are large game animals such as bison, horse, mammoth, and reindeer. Many paintings are on prepared surfaces and are colored with ochre; all reflect artistic talent, though the precise purpose of the paintings is unknown. Music was also part of the lives of Neanderthals and modern humans. When, how, or why it developed is not known, but the oldest instruments, a flute made from the femur of a cave bear found at Divje Cave in Slovenia and the less-contentious bone pipe from Geissenklösterle in Germany, are circa 43,000 and 36,000 years old, respectively. Music may be linked with language, which is a distinctly human trait. There is much debate as to when it developed and whether the ancestors of modern

humans were able to communicate via the spoken word, a capacity that would have conferred considerable advantage for all human activities through the sharing of knowledge and the facilitation of the division of labor.

Lifeways in Sub-Saharan Africa

During the Upper Paleolithic, hunter-gatherers in sub-Saharan Africa began to adopt more intricate weapons such as the bow and arrow, which gradually replaced the use of flake tools and core that had been characteristic of the Middle Paleolithic. Moreover, the lifeways that had been adapted by sub-Saharan hunter-gatherers, while comparatively similar to their hominid forbearers, had a greater level of complexity in terms of more innovative tool kits and social organization. While these hunter-gatherer bands relied on game and foraging for their subsistence, they developed hunting techniques that required social organization and increasing levels of cooperation within the group. Nonetheless, the sub-Saharan natural environment shaped the character of the lifeways of early human societies, given the region's available resources and geographical makeup.

Homo sapiens sapiens is estimated to have emerged from Africa between 200,000 and 130,000 years ago, thereby displacing other hominids in the rest of the world. Around approximately 60,000 years ago Africa remained home to modern humans, while other hominids, particularly *Homo erectus* and Neanderthals, were in Asia and Europe, respectively. Quite gradually, small groups migrated out of Africa to nearby continents suitable for human habitation after climate changes.

Early human societies in sub-Saharan Africa relied on foraging for much of their subsistence, living off the available flora and fauna of the region. The adaptability of these early societies allowed them to exploit different sources of food

and develop different tool kits to allow them to extract resources from the environment in terms of hunting, food processing, and the manufacture of implements from stone and other raw materials.

During the Late Stone Age, previously uninhabited regions such as the Congo River basin began to be populated. Some early human communities developed portions of the landscape to accommodate sedentary lifeways centered on agriculture. Through the use of fire as a way to clear brush and forests, thereby establishing dominion over the land, these early settlements developed farmland and grazing fields. Early artwork found in the region depicts a variety of foraging and hunting activities, as these remained the primary more of human sustenance in sub-Saharan Africa regardless of the evolving lifeways for sedentary agricultural communities. Moreover, these also suggest the beginnings of more complex behavior in regard to human beliefs and understandings of the natural world.

During the Neolithic, some sub-Saharan societies developed more complex and diverse settled communities. Agricultural surpluses allowed for the establishment of craft specialization outside of agriculture, the development of political structures, and the creation of more complex belief systems. Through this process humans domesticated both plants and animals, selecting both seeds and breeds that illustrated desirable characteristics and ensured survival and adaptability to human needs. The clearing of fields and forests continued along a more systematic course of landscape development as settlements increased in size and density. Livestock was maintained as an integral source of sustenance and was provided with food and protection from predators.

Given the geographical characteristics of much of sub-Saharan Africa, the diffusion of livestock domestication took root for various semi-sedentary groups as a viable lifeway shaped by the ecological makeup of the landscape. While agriculture developed in this region, it was not to the same extent as in North Africa or Mesopotamia. The Congo River, Upper Nile, and Niger River valleys as well as other viable supplies of water did allow for the creation of several agricultural communities in the sub-Saharan Neo-

lithic. However, much of sub-Saharan Africa remained characterized by hunter-gatherer societies and growing pastoral communities with livestock. Environmental concerns and niches shaped the type of lifeways that African societies chose for their sustenance. The increasing variety of lifeways as well as the mounting complexity of African societies amid the dynamic changes occurring in human lifeways made sub-Saharan Africa's genetic diversity far more complex historically than other world regions.

Advances in stone technologies, such as grinding stones, composite tools, and pottery, emerged among various sub-Saharan cultures during the Neolithic. While many of these were based on antecedents in earlier societies, they were also indicative of the increasing complexity of African societies of this period in terms of cognitive abilities and evolving human behavior. Moreover, artwork and the development of language groups also are illustrative of this dynamic change occurring as societies came into contact with each other, thereby diffusing their cultural characteristics across the region while also developing their own individual niches and forms independently.

Lifeways in the Levant and Middle East

As the present interglacial, the Holocene, began circa 10,000 years ago, environmental change was occurring at a relatively rapid rate as global temperatures rose. As was the case when earlier ice ages terminated, ecological changes were occurring in response to this climatic stimulus as plant and animal species and communities adjusted to interglacial conditions. However, the

Aerial view of the archaeological site at Çatalhöyük, a Neolithic farming settlement. Discovered in the 1950s, the ruins are in present-day Turkey on the Konya Plain. The site is currently being excavated by an international team of archaeologists. (Yann Arthus-Bertrand/Corbis)

opening of the Holocene was a period of substantial socioeconomic change within human communities. This was associated with the alteration of strategies for food acquisition and had profound effects on the environment and society. The technology of agriculture was emerging, with the earliest evidence for plant and animal domestication coming from the Levant. From this region, crops and domesticated animals as well as the principles of agriculture spread into Europe, Africa, and Asia. This was a major watershed in human development and its influence on the global carbon cycle.

What caused people to domesticate certain plant and animal species remains enigmatic. Speculation focuses on pressure from rising population or increasing scarcity of resources due to environmental change or possibly a combination of the two. In the Levant and the Middle East, cereals such as wheat and barley, pulses such as lentil and pea, and fruit trees, notably the fig, were among the first plants to be domesticated, circa 10,500 years ago. Today, the cereals and pulses constitute major crops in world agriculture, while sheep, cattle, and goats, all domesticated by circa 8,000 years ago in this region, remain the most widespread livestock. While hunting and gathering continued to play an important role in human communities, agriculture encouraged permanent settlement. It

also required clearance of natural vegetation, soil preparation, plant and animal selection and breeding, and planning and management as well as labor. It most likely encouraged a degree of diversification of lifeways within and between human groups, with some people engaging in crop cultivation, others in herding, and yet others in hunting, with overlaps between groups that also exchanged produce and were elements in an increasingly complex trading system. Some groups may have practiced a form of transhumance, that is, spending some time taking animal herds to distant pastures for part of the year.

The increasing sedentarism (nonmigratory status) of human groups necessitated by crop cultivation encouraged the construction of nucleated permanent settlements that became widespread in the region by circa 8,000 years ago. Each housed approximately 100–200 people. Sun-dried brick houses with a stone foundation and roofs made of reeds, walls, communal storage pits for grain, and hearths were characteristic of these settlements. Some dwellings have shrines, suggesting religious practices, and some contained the skeletal remains of humans buried under floors or in walls. These included skulls with faces made from plaster and shells to represent eyes and may reflect a form of ancestor worship. Such settlements imply enhanced cooperation for mutual benefit between family groups, exchanges of resources, and possibly shared beliefs. Archaeological excavations of sites such as Jericho and nearby Netiv Hagdud in the Jordan Valley, Abu Hureyra in the Euphrates Valley of Syria, and many settlements throughout the Fertile Crescent (the Middle East, Levant, Turkey, western Iraq, and Iran) such as Çatalhöyük in Turkey provide detailed information on the transition from a hunting and gathering society to an agricultural society. Even in the latter, the wild food resources from woodland, and the lake and steppe, played a significant role in food acquisition. Jericho and Çatalhöyük, which are atypical of early Neolithic villages because of their large size, rapidly developed into urban centers. The lower layers of Jericho indicate a population of approximately 300, but later Neolithic layers suggest a population of several thousand. The shift to agriculture is well marked at Abu Hureyra, where hunter-gatherers settled

circa 11,500 years ago; they focused on wild gazelle and grassland plant species and lived in pit dwellings. Within a millennium another settlement had emerged whose inhabitants were engaged in herding domesticated sheep and goats and in cultivating wheat, barley, and pulses. They lived in aboveground dwellings comprising multiroom single-story rectangular structures with decorations and plaster floors built along narrow lanes. Charcoal deposits from hearths indicate that wood from willow, poplar, maple, and tamarisk was being used as fuel. Human skeletons, especially of females, reflect bone conditions associated with kneeling and food preparation such as cereal grinding. Public buildings and monuments, some with carvings and decoration, were also present, indicating communal activities and organization.

Many ancient sites also reveal evidence for other innovations and trade. For example, the tool assemblages of Abu Hureyra comprise flint flakes and scrapers plus awls, needles, arrowheads, and pins made from animal bone and include stone grinding tools. Tools made from obsidian, a glasslike product of volcanic activity, are also present at many sites. It was valued for the sharp edges that could be produced by flaking and was traded throughout the region from sources in Anatolia and Cappadocia, both in Turkey. Tools made of basalt, from the Red Sea region, are also present. Evidence for artistic development and possibly a form of religion comprises a huge range of female figurines and bulls made from clay. The earliest figurines come from Netiv Hagdud, where a village of oval and circular mud-brick houses was constructed almost 10,000 years ago and whose inhabitants became engaged in the cultivation of domesticated barley.

Another significant innovation was the development of pottery that postdates the initiation of agriculture. The earliest pottery from the Levant/Middle East is circa 8,000 years old. Once introduced, it spread rapidly and became increasingly sophisticated in terms of pattern and coloring. Examples include pottery with a herringbone pattern that was painted red from the artifact-rich Neolithic villages of Sha'ar Hagolan and Munhata. A wide range of vessels were produced in distinct centers using pit or kiln fires and

traded throughout the region. This plus the wide variety of tools and art forms reflects specialization within a rural society with the emergence of specialist craftspeople. Burial practices also changed; instead of interment in houses, burial grounds were established outside villages.

Lifeways in East Asia, Southeast Asia, and Austronesia

During the glacial epoch, there were three major landmasses in East Asia: East Asia proper (what is now primarily modern China); Sundaland, which was composed of what are known today as the islands of Indonesia and Borneo; and Sahul Land, which was composed of New Guinea and Australia. Sundaland was connected to the East Asian landmass. Sundaland and Sahul Land were always separated by the very deep waters of the Wallacea Straits. The modern configuration of islands, both large and small, appeared around 10,000 years ago.

To understand this geography is important, because it meant that many places that are islands today were once connected to larger landmasses, and therefore they could have been colonized by foot-mobile peoples. Thus, our ancestors could have moved easily into Sundaland from East Asia, whereas moving from there into Sahul Land would have always required the use of some sort of watercraft. Just how this was accomplished remains speculative, but most probably it was done by island hopping. Even at optimal times for crossing, watercraft would have had to move across distances of 18.6 to 55.9 miles (30 to 90 kilometers) over open ocean. This would have been daunting until the appearance of navigational technologies and reliable watercraft, and it seems clear based upon multiple lines of evidence that *Homo sapiens* would have been the only species capable of moving over these distances.

This argument is confirmed by the archaeological evidence from the region. Although there is speculation, based upon DNA evidence, that anatomically modern humans were present in the region well before 50,000 years ago, archaeological data suggest that an occupation of the region after 50,000 years ago is more probable, especially for Sundaland and Sahul Land.

After 40,000 years ago, *Homo sapiens* was present in most of East and Southeast Asia. Although *Homo erectus* had colonized the region at a much earlier date, possibly as early as 1.5 million years ago, studies of the skeletal morphology of the remains encountered by archaeologists suggest that *H. erectus* had gone extinct well before the arrival of our species in the region, thus demonstrating that *H. sapiens* had migrated into the region from elsewhere and had not evolved locally from *H. erectus*. However, the recent discovery of a diminutive species, *Homo floresiensis* (nicknamed the Hobbit), found on the Indonesian island of Flores, complicates our understanding of the relationships of these species. Some have argued that *H. floresiensis* is a direct descendant of *H. erectus*, while others suggest instead that it is a local variant of *H. sapiens*. To date, the bulk of the data support the inference that *H. floresiensis* is more closely related to *H. erectus*, although the specifics of that relationship remain unclear.

One of the most important sites in Sundaland is Niah Cave on the modern island of Borneo, where a skeleton of an anatomically modern human (that of an adolescent girl) was found and dates to around 40,000 years ago. There are earlier deposits in the cave that do not contain skeletal remains but show evidence of an intensive occupation of the site. Niah Cave thus provides a clear baseline for the occupation of Sundaland that dates to 50,000–40,000 years ago.

Archaeological data from Sahul Land show that the landmass was the scene of an intensive wave of occupation around 40,000 years ago, the source of which was Sundaland. There is a clear north-to-south trend in this occupation, with dates in northern Sundaland slightly earlier than those in the south. However, even the most widely separated dates are not separated by more than a few thousand years, suggesting a

➤ EARLY AUSTRALIAN HUNTER-GATHERERS

Homo sapiens arrived in Australia when it was part of a larger continent (Sahul) that included New Guinea, Tasmania, and lands now under water. This was 45,000–60,000 years ago; the older dates are still disputed. By about 40,000 years ago archaeological sites occur in all corners of the continent except Tasmania.

Late Pleistocene Sahul was populated by more than 50 species of large animals that are now extinct. Did arriving humans kill them off? There is no scientific consensus. Arguments can be found in favor of (a) a rapid killing blitzkrieg, (b) extinctions over the next 30,000 years, (c) climatic causes, and (d) nearly all being extinct before human arrival. At only one site, Cuddie Springs, is there any likely evidence for a smoking gun relation between humans and extinct animals, and even this is still strongly disputed.

Archaeological evidence shows that Pleistocene Australian's behavior was fully modern. At Lake Mungo, an extended burial, covered with powdered ochre brought from more than 124 miles (200 kilometers) away is dated to 40,000–45,000 years ago. About 30,000 years ago a young woman was cremated, the oldest cremation in the world. People here were camping near the lake, collecting freshwater shellfish, fishing (possibly with nets), and hunting small animals. They made shell beads, bone points for their spears, and stone artifacts, as did people in other parts of the continent.

Current evidence shows that Tasmania was occupied only less than 35,000 years ago. There, people were living in a very cold subalpine environment, often in caves and rockshelters. As hunters, they specialized in the highly territorial red-necked wallaby (about 33 pounds, or 15 kilograms), which supplied at least 85 percent of their meat.

very rapid colonization that spread quickly to the most favorable habitats on the landmass. Key sites include Malakunanja rock shelter and Lake Mungo, where the remains of an intentionally buried anatomically modern human, most probably an adult male, were discovered.

No matter their location, the lifeways of the peoples of East Asia, Sundaland, and Sahul Land were those of mobile hunters and gatherers.

Many settlements were located along the major rivers of the region, and there is some evidence that coastal settlements were also of importance. Much of southern East Asia and all of Sundaland at this time were covered in tropical forests, and it is important to note that while *H. sapiens* was able to successfully adapt to this difficult habitat, *H. erectus* was unable to do so.

Lifeways in Inner Asia

Inner Asia, or the interior of the Eurasian landmass, is composed of the five independent central Asian republics of Uzbekistan, Turkmenistan, Tajikistan, Kyrgyzstan, and Kazakhstan; the republic of Mongolia; the Xinjiang Uygur, Inner Mongolia, and Tibet Autonomous Regions of the People's Republic of China; and adjacent parts of Afghanistan, Pakistan, Iran, China, and Siberia in the Russian Federation. The environments of this vast region are highly varied and include large expanses of desert; high plateaus and mountains; large, relatively flat river basins; subarctic tundras; and large expanses of open plains, or steppes.

Inner Asia remained unoccupied by humans until relatively late in prehistory, sometime after 50,000 years ago. Although *Homo erectus* remains have been discovered in western Eurasia as early as 1.7 million years ago at the site of Dmanisi in the Republic of Georgia, the species apparently ventured no farther north. That Inner Asia was colonized so late in great part can be attributed to the harsh environmental conditions that persisted in the region for most of the Pleistocene. Although most of Inner Asia was not covered in ice during the glacial epoch, it was very cold and dry until around 50,000 years ago, and resources attractive to our ancestors were sparse. Furthermore, the extreme cold of many areas of the landmass would have required well-tailored clothing, which was not made by our ancestors until roughly this date.

After 50,000 years ago, however, the climate of Inner Asia, while still harsh, nevertheless im-

proved. Grasslands attractive to large herbivores, such as mammoth, bison, and horse, became widespread. Anatomically modern humans (*Homo sapiens*) moved from an as-yet poorly identified region of Southwestern Asia and into Inner Asia. Although there are no sites known from the time period of 46,000 to 32,000 years ago on the East European plains, there are sites present during this time period farther to the east in the Altai Mountains and south-central Siberia. The tools used by these peoples are characteristic of the Upper Paleolithic. Arctic Siberia shows clear signs of habitation by 30,000 years ago, as does northern Mongolia. Although there have been claims of an early human presence on the Tibetan plateau as early as 50,000 years ago, these have yet to be verified. However, the Chusang site located near Lhasa has been dated to 30,000 years ago and thus provides some evidence for an early occupation of the high plateau.

Many areas occupied by humans during the relatively benign period from 46,000 to 22,000 years ago were either abandoned or used only sporadically from 22,000 to 17,000 years ago, a period known as the Last Glacial Maximum. Ice sheets moved farther to the south in the Northern Hemisphere, and this created very cold temperatures and very dry conditions across much of Inner Asia. It is likely that the Tibetan plateau was abandoned at this time, and many groups that had lived at more northerly latitudes in Siberia moved to the south.

As the glaciers began their retreat around 17,000 years ago, the climate across Inner Asia improved dramatically. Much of Siberia, except for the most northerly latitudes, was reoccupied as early as 21,000 years ago. However, settlement patterns reflect a highly mobile lifeway, indicating that resources were not yet of sufficient density for longer, more permanent occupations. Similar lifeways characterized most of Inner Asia at this time. Much of the coastal Russian Far East was also occupied at this time. Small groups of hunting and gathering peoples entered Mongolia from the north after 18,000 years ago, and by roughly 15,000 years ago groups of foragers had reoccupied the northeastern margins of the Tibetan plateau.

In Siberia, river basins became the focus of intensive human occupation. Fishing, using

barbed harpoons, became widespread, and the high-resource densities supported settlement patterns characterized by reduced mobility. Similarly, the coast of the Russian Far East saw the appearance of subsistence systems based upon salmon harvests. Settlements in the Amur Basin began making ceramics as early as 13,000 years ago; these artifacts show great similarity to those made by the Jomon culture of Japan, suggesting widespread contacts between these areas. Finally, around 10,000 years ago, hunters and gatherers of the Sumnagin archaeological tradition penetrated the arctic tundras of northern Siberia for the first time.

Lifeways in Western and Eastern Europe

Anatomically modern humans (*Homo sapiens*) entered southeastern Europe sometime around 47,000 years ago from a source area somewhere in southwestern Asia or the Levant. At this time, much of southern Europe was occupied by Neanderthals, a species that had been present there for thousands of years, and there has been much speculation about the nature of relationships between these two species.

This period of the occupation of Europe is known as the Upper Paleolithic, and the archaeological culture carried by these newcomers is known as the Aurignacian, first defined from excavations at the Aurignac rockshelter in the French Pyrenees. Defined primarily by the types of stone tools used by these peoples, the Aurignacian was present across much of Europe by 35,000 years ago. Among the other tools used by these peoples were bone and antler projectile points (most likely used to tip spears), bone awls,

fire-making drills, and bone needles (some with eyes). Needles and awls are tools commonly thought to be associated with the manufacture of well-tailored clothing, which makes its first appearance in Europe. Such clothing would have helped Aurignacian peoples adapt to the relatively cold climate of Europe at this time. There is also evidence of items of personal adornment such as beads made of bone, drilled animal teeth, and marine shells. The latter indicates the existence of trade and exchange networks at this very early date. There continues to be debate as to whether some of the art found at Chauvet Cave dates to this period. If the dating is accurate, this would be the earliest rupestral art known from Europe and quite possibly the world.

Tool assemblages in eastern Europe, best represented by those found at the Kostenki site along the Don River in Russia, reflect something different. Although most archaeologists would describe them as being of Upper Paleolithic origin, they are distinct when compared to the Aurignacian, and some have argued that the tools found at the site were made by a different group of anatomically modern humans who began a migration into Europe from a different source than those who made typically Aurignacian tools. These findings suggest that Europe may well have been colonized by migrants from many sources from the Middle East or southwestern Asia instead of a single wave of people moving into the continent.

The period from 35,000 to 29,000 years ago is thought by some archaeologists to be a transitional period in European prehistory. That is, there are a number of stone tool traditions found scattered across Europe that have characteristics thought to have been created by Neanderthals that were contemporary with Aurignacian tool traditions. Many of these local traditions may reflect remnant populations of Neanderthals that finally disappeared from Europe sometime after 28,000 years ago.

The Gravettian archaeological culture is found across Europe from 28,000 to 21,000 years ago. The artifacts created by the peoples of this time are thought to reflect a mature adaptation to the climatic and social conditions found across Europe at this time. Composite tools made of bone or antler and stone become common, and a

► MAMMOTH HUNTERS OF THE RUSSIAN PLAIN

The examination of settlements of mammoth hunters of the central part of the Russian Plain had become a subject of special study as early as the late nineteenth century when sites such as Gontsy, Mezin, Mezhirichi, and Kostenki were discovered and the results of their study put into scientific circulation. Nowadays, about 100 sites, most of which date to the late Valdai period (25,000–10,000 BCE) are known from two main areas: (1) the Russian Plain and the Middle Dnieper River basin and adjacent territories and (2) the so-called Kostenki-Borshevo region in the Don River basin. Studies by many recent scholars have defined aspects of the livelihood and subsistence strategy and art and ideology of these ancient mammoth hunters.

These hunters lived in large base camps with significant concentrations of population where long-term dwellings made of mammoth bones, food storage pits, tool production areas, meat (food) processing zones, and hearth zones were discovered. Questions about duration of occupation, seasonality, and reoccupation of these base camps remain unresolved, and there is no clear idea about how these hunters survived the very cold conditions of the Last Glacial Maximum. The subsistence strategy of these peoples was based on collective hunting of large gregarious herbivores (mammoth, woolly rhinoceros, musk-ox, horse, reindeer, bison), fur-bearing species (arctic fox, wolf, bear, hare), and, rarely, predators (cave lion, hyena, lynx).

This subsistence strategy implies the existence of large agglomerations of population at these base camps necessary to realize collective hunt-

ing, while the presence of a series of small specialized sites around the base camps (tool production sites, short-term camps, and so on) indicates the possibility of seasonal population dispersion or movement.

The mammoth hunters of the Russian Plain engaged in highly developed artistic and creative activity through the creation of mobiliary (or movable) art. They made small (approximately 2–4 inches, or 5–10 centimeters in height) female figurines made of mammoth tusk, so-called Paleolithic Venuses, relatively realistic in the Kostenki region and more stylized in the Middle Dnieper region. These are thought to have been connected with fertility cults. They also made spectacular engraved and/or ornamented bones, antlers, and stones. Another genre of mobile art objects is represented by different kinds of personal decoration (bracelets, pendants, diadems, beads, and so on) made of bone, tusk, antlers, fangs, and rare stones, often interpreted as different sorts of amulets connected with specific forms of fetishism and used for magical individual protection. The earliest musical instruments in eastern Europe included striking, sound, and wind instruments (such as fife, reed, flute, and tomtoms). These were found inside a large construction made of mammoth bones at Mezin and have been interpreted as evidence for collective ceremonies including dances, songs, and music.

stone tool technology based on the production of prismatic blades is characteristic of the Gravettian. Bone tools indicative of the production of clothing continue to be found, and for the first time in Europe substantial heated structures have been discovered. At Kostenki, for example, semi-subterranean structures surrounded by mammoth bones were discovered. There is evidence of storage facilities in some sites of this period as well. In the winter climate of Gravettian eastern Europe, storage indicates the existence of camps occupied for longer periods of time. Some sites

also have evidence for the use of stone lamps that used animal fat as a fuel. At Dolni Vestonice (now in the modern Czech Republic), impressions left in clay that have been dated to 27,000 years ago are suggestive that cordage and baskets were used by these peoples.

The interment of the dead becomes more common in Gravettian times. One of the most interesting of these burials comes again from Dolni Vestonice, where three young adults were buried in a common grave. Each had necklaces made of teeth around their heads, and the ground upon

➤ REINDEER HUNTERS OF FRANCE—PINEVENT

The remains of a seasonally occupied camp of reindeer hunters at Pincevent (department of Seine-et-Marne, France) were discovered in 1964, and since that time this site has become one of the most illustrative examples of the lifeways and subsistence strategies of Magdalenian peoples at 13,000 years ago. Excavations under the supervision of Andre Leroi-Gourhan through 1985 have contributed greatly not only to our knowledge of early prehistoric culture but also to fieldwork methodology.

The site was occupied seasonally during the warm period of the year, when the reindeer crossed this locality in the course of their repeated migrations. Stored meat was consumed during the time between hunting episodes along with some aurochs (wild oxen), red deer, small game, fish and mollusks, and plants obtained through gathering. The site was occupied repeatedly, attesting to the successful nature of this lifeway.

Life at the settlement was concentrated around a central hearth, which contained plenty of burnt

bones and very little wood. Hearths were the focal point for most domestic activity. On the basis of patterns of artifact distribution, it appears that the site contained four circular structures, most likely tentlike dwellings.

which they were buried had been covered in red ochre, a pigment commonly used at this time in burial contexts.

Art of all different kinds is also commonly found at Gravettian-era sites. Much of the famous rupestrian art found in the caves of western Europe dates to this period, as do the bulk of the famous "Venus" figurines. Many artifacts of unknown function carved from mammoth ivory have also been discovered.

Around 21,000 years ago, the Gravettian is replaced by an archaeological tradition known as the Magdalenian, which lasts until roughly 10,000 years ago. The appearance of this tradition coincides with the onset of the Last Glacial Maximum, a period of intense cold across the Northern Hemisphere. Many areas of northern Europe that had been occupied during the Gravettian were abandoned, most likely due to the advance of glacial ice sheets that created an increasingly harsh climate even for peoples who had warm clothing, food storage, and robust shelters.

A number of technological innovations characterize the Magdalenian. It is thought that the

bow and arrow may have been invented at this time, although the evidence for this is indirect and based upon the presences of small, light, leaf-shaped points that would not have served well as tips of thrusting or throwing spears. There is less doubt about the invention of the spear-thrower, a tool that allows its user to hurl a spear longer distances with more accuracy than when thrown by hand. Barbed bone points, and possibly harpoons, are found at some Magdalenian sites in western Europe, and bone fish hooks are found in central Europe. These tools reflect the widening of the range of species that our ancestor began to use at this time. Yet another innovation, again found in western and eastern Europe after 18,000 years ago, is the domesticated dog, which is the first species known to have been tamed by humans.

After 18,000 years ago, which marks the end of the Last Glacial Maximum across the continent, most of the regions abandoned had been reoccupied. The circulation of artifacts, mostly lithics, across Europe attests to the importance of social networks that had become common-

place at this time. Although such networks were known in the Gravettian, their scope becomes much larger during the Magdalenian.

Art of all kinds is very common during this period, and some of the most spectacular cave art found in Spain and France dates to this period. Objects made of ivory and stone are also abundant at many Magdalenian sites. Some archaeologists have speculated that notched and carved bones may have served as calendars. Personal adornment is also commonly found in the burials of this period. Although the reasons are still debated, it is clear that the Magdalenian reflects a significant increase in social complexity in Europe at this time.

Lifeways of the First Americans

Evidence has yet to be found that would provide a clear picture of the lifeways of the first Americans. Historically, most specialists believed that the first Americans were highly mobile hunters and gatherers who focused most of their subsistence economy on large mammals. This led several researchers, following Martin (1982), to propose a blitzkrieg model whereby the first Americans were hypothesized to have funneled into the New World, causing the extinction of more than 35 mammalian species. Evidence from Monte Verde and other sites, however, suggests that the picture is not as simple and that the first Americans followed different lifeways depending on ecological conditions.

Archaeological sites predating 12,000 years before the present have unfortunately been able to provide only glimpses of the lifeways of the first Americans. Current evidence indicates that the first Americans had a general, as opposed to specialized, tool kit and subsistence economy,

MONTE VERDE AND THE CLOVIS CONTROVERSY

Monte Verde, located on the southern end of South America, has provided irrefutable empirical evidence that the Clovis-First model is no longer viable. The Clovis-First model, historically favored, argues that the first Americans came into the Americas shortly after 12,500 years ago and followed a big-game subsistence economy. The Monte Verde site, which predates Clovis by 1,000 years, is a 12,500-year-old settlement along the banks of what is now Chinchihuapi Creek in Chile. Organic and inorganic artifacts were recovered from Monte Verde, including bones, various types of plant matter, and an array of simple flake tools and bifacially flaked stone tools. In January 1997 several leading specialists spent 11 days scrutinizing the Monte Verde site to examine its integrity; at the end of the examination period a consensus was reached that the stratigraphy was good and the radiocarbon dating of the site correct. The evidence from Monte Verde argues that people migrated into the Americas far earlier than previously thought under the Clovis model, sometime before 13,000 years ago. Furthermore, the Monte Verde evidence supports the conclusion that early migrants to the New World much more sophisticated and their complex lifeway patterns and technologies were more developed than were under the simplistic Clovis model.

which was thought to be the case under the now-defunct Clovis model. This general tool kit and subsistence economy were used in the development of various specialized adaptive patterns that fit particular environmental contexts and included the ability of first Americans to exploit and adapt to a wide range of environments and their resources.

For example, in the western U.S. deserts of the Great Basin, evidence indicates that Late

Pleistocene peoples not only exploited a range of floral and faunal resources but also specifically targeted smaller fish in their subsistence quest. Analysis of fish remains from the Stillwater Marsh area indicates that small tui chub were a major food resource for inhabitants of the region. The subsistence economics of this lifeway, adapted to an arid desert and a lacustrine environment, further entailed that these late Pleistocene peoples gathered, transported, and stored a wide variety of other resources.

Likewise, evidence from up and down the Pacific coast of the Americas indicates that Late Pleistocene peoples followed a lifeway pattern that was based on available seasonal resources. For example, California's Channel Islands provide evidence for early maritime activity by the first Americans, including the use of seaworthy boats. Numerous early shell middens have been identified along with a relatively large assemblage of bifaces, chipped stone artifacts, shell beads, worked bone, and well-preserved faunal remains. This evidence indicates that the first Americans' lifeway pattern for the Pacific coast consisted of subsisting on mussels, abalones, and other shellfish from the rocky intertidal areas as well as fish, sea mammals, and sea birds when available.

In the vast plains of North and South America, on the other hand, evidence indicates that Late Pleistocene peoples relied on large mammals for much of their subsistence, clothing, and other resource needs. For example, Arroyo Seco, located near the city of Tres Arroyos in Argentina, is a multicomponent site that provides evidence indicating that hunter-gatherers used mostly quartzite flakes with some unifacial retouching in the pursuit of large mammals. The lithic remains were found associated with bones of modern animals and extinct Pampean megamammals, indicating a primary adaptation to guanaco, extinct horse (*Equus*), giant sloth (*Megatherium*), and deer as the economic basis of subsistence for the first Americans of the region.

The first Americans not only relied on a wide and diverse array of large sized flora and fauna but, according to zooarchaeologists, may have also exploited small mammals, insects, and aquatic species. Individually, these resources did not provide enough energetic return to be col-

lected, but when harvested in mass quantities by a cooperative group, they provided enough subsistence to be worth the time and effort.

Beyond the subsistence economies of the first Americans, little is known concerning social, religious, or economic aspects of their lifeways. Researchers have hypothesized that when resources became scarce due to climate changes, populations became more dispersed across the landscape and social networks broke down, while during more resource-rich times, population growth and settlement nucleation occurred. Furthermore, because of the instability of many environments, many first American groups practiced forms of out-migration to more resource-abundant areas along with population adjustments that involved intermarriage and reciprocity arrangements. However, most first American peoples followed a cyclical lifeway pattern when possible, preferring to stay within known and familiar environments.

Two theories have been put forward as to how these intermarriage and reciprocity networks functioned. In the band-macroband model, the first American lifeway pattern is considered to be strongly shaped by the environment, specifically seasonal and geographic variation in resources. The staging area model, on the other hand, argues that colonizing populations of first Americans settled into resource-rich areas fairly quickly and used them as bases from which to familiarize themselves with local resources as well as to explore and settle the surrounding region.

■ Introduction: Lifeways after the End of the Glacial Epoch, 10,000–4000 BCE

The lifeways of prehistoric communities worldwide between 10,000 and 4000 BCE can be broadly classified into two groups: hunting-gathering and farming. This distinction places food acquisition as the major force in human activity, not least because it underpins most aspects of social activity as well as facilitates trade and structures the division of labor. By 10,000 BCE most prehistoric communities continued to engage in hunting and gathering, which had become increasingly sophisticated since its adoption by *Homo erectus* circa 1.5 million years ago. However, at the dawn of an interglacial epoch, the Holocene, circa 8000 years BCE, significant changes were occurring in terms of the manipulation of plants and animals as food sources in the Near and Far East. The domestication of specific wild plants, notably grasses, was under way, as was clearance of natural vegetation as agriculture slowly developed. The domestication of specific animals was also occurring by this time, especially in the Near East where domesticated cattle and sheep originated. Further domestications took place in other regions at later times but mostly between 8000 and 4000 BCE. These include sub-Saharan Africa, Central America (Mexico), the northern Andes, and east-central North America. Changes in other aspects of society also occurred including permanent settlement, the production of pottery, diversification of resource use as metal smelting developed, and innovations in art forms and jewelry.

Hunting and gathering were the most widespread means of food acquisition circa 10,000 BCE. Paleolithic peoples worldwide used wood and stone tools for hunting, but as the last ice age ended, tool kits altered. Innovations included in-

creased tool diversity and the production of microliths (i.e., small scrapers, blades, and points that would have been hafted in wood). In some regions there was also an increase in tools made from antler and bone. In Europe such innovations appear to have been a response to a changing environment, notably a shift from relatively open habitats to early interglacial forests, and have led archaeologists to describe the culture as Mesolithic or Middle Stone Age, which lasted until circa 5000 BCE. In the Near East this stage is not represented, and the Paleolithic gave way to the Neolithic or New Stone Age, which is associated with the inception of agriculture. Mesolithic cultures comprise the Maglemosian in northern Europe, the Beuronian in central Europe, the Epigravettian in the Mediterranean zone, and the Sauveterrian in western Europe. Star Carr in Yorkshire, Britain, is a particularly important archaeological site, and excavations have yielded artifacts that provide an insight into Mesolithic lifeways. The habitation site consists of a platform of cut birch brushwood that was constructed in reed swamp at the edge of a lake; this platform may have been covered by animal skins to create tentlike structures. Bones from numerous animals such as badger and fox, which were possibly trapped for their fur, and various birds reflect the regional fauna, while bones from red deer, roe deer, elk, aurochs, and boar represent food sources. Bones of domesticated dog, the earliest domesticated animal found in Britain and the earliest domesticated animal in general, were also discovered, and it is likely that the species was used for hunting and guarding as it was elsewhere. Star Carr may not have been permanently occupied but rather may have been used

intermittently or seasonally by hunter-gatherers who also exploited coastal resources, used fire, treated animal skins, and made microliths; they may also have engaged in ritual practices, as indicated by the presence of stag frontlets with attached antlers. In Scotland, including the Scottish Islands, and along the European coasts of the North Sea, there is widespread evidence for Mesolithic exploitation of large mammals, especially species of deer, and coastal resources including mollusks, fish, and sea birds. At some sites bows made from elm, rowan, and yew have been found. Mesolithic communities constructed boats; both boats and paddles have been preserved. At Tybrind Vig on the Danish island of Fyn, deposits dating to between circa 7500 to 6000 BCE contain two canoes of circa 19.6 and 31.1 feet (6 and 9.5 meters) long made from the trunks of lime trees, decorated paddles, a great variety of bone, antler, and wooden artifacts, and fishing equipment as well as amber and a range of animal and plant remains. The latter include hazelnuts, sea beet, and acorns, which are present in many European Mesolithic sites along with water chestnuts.

By 9500 BCE in the Near East, changes were occurring that would have profound repercussions for both the environment and society. Archaeological excavations at many sites in the Near East, such as Jericho, Netiv Hagdud, Abu Hureyra, and Çatalhöyük, have revealed that lifeways were changing substantially, including the establishment of permanent settlements. Other changes involved the domestication of specific plants and animals and the inception of the first agricultural systems. This occurred in the Fertile Crescent of the Near East, a region incorporating the land adjacent to the eastern Mediterranean and the valleys of the great Indus and Euphrates rivers. The major crops domesticated included emmer and einkorn wheat, barley, oats, and rye, the ancestors of which are sometimes described as founder crops that were present in the region as wild grasses. A variety of legumes were also domesticated, such as the lentil, chickpea, and broad bean, along with the olive and fruits such as the fig. Animal domestication was also occurring; sheep, goat, cattle, and pig were all domesticated between 7000 and 5000 BCE.

Their ancestors were the mouflon, beozar goat, auroch, and wild boar, respectively. The Early Neolithic people responsible for this selection and domestication were also hunter-gatherers who began to adopt a more sedentary lifeway as farming became established, although hunting and gathering continued for obtaining additional sources of food. There is much speculation as to why this new lifeway of farming began, especially as it requires forward planning and is labor-intensive. Environmental change, which may have affected the availability of wild food plants and animals, and increasing population pressure are two likely reasons, or possibly the stimulus was linked to territory and the need to improve food security or to generate a food surplus for trade.

Neolithic people also practiced rituals, as evidenced by human figurines and plastered skulls found at some sites. The early farmers did not have pottery and belong to a period circa 8500 to 7500 BCE that is known as the prepottery Neolithic. It is distinguished from the earlier Natufian period by a more varied stone tool assemblage, including an increased range of pounding and grinding tools. Pottery making dates from 7500 BCE and marks the establishment of a new technology in the region. Settlements continued to grow and diversify as agriculture expanded. By 5000 BCE new technologies were developing, namely metal smelting, that initially involved the exploitation of copper ores, which gave rise to the Copper Age and the Bronze Ages, and later iron ores. Jewelry made from stone, clay, bone, and shell and later from metals was also produced. Such technologies broadened the range of goods for trade and reflect the increasing sophistication of societies in which craft specialization occurred. Agriculture thus allowed a proportion of society to engage in activities other than food acquisition. From the Fertile Crescent agriculture spread into Europe, Asia, and Africa, where it became a major cause of environmental change and especially of deforestation.

Much less research has been undertaken in other regions where plant and animal domestication occurred, so how lifeways altered is less well understood. Nevertheless those selected

plants and animals have had a profound impact on ecosystems and landscapes as well as on human lifeways. For example, China is considered to be the home of rice and millet, both domesticated from wild grasses. Where and when rice was domesticated is contentious, but it probably occurred in the Yangtze River basin and/or the delta; age estimates vary between 8000 BCE based on work at Diaotonghuan Cave near Poyang in the Middle Yangtze basin and at Shangshan, a Neolithic village in the Lower Yangtze valley, and 4900 BCE based on work in the Zhejiang region, also in the Lower Yangtze. The earliest date of 4500 BCE for domesticated millet comes from an early farming village of Dadiwan in northwestern China. The three centers of plant domestication in the Americas produced maize, capsicums (chili pepper), potato, and various squashes prior to 4000 BCE. All have become major world crops. The earliest evidence for maize domestication comes from the Xihuatoxtla rock shelter in the Rio Balsas valley of the Mexican state of Guerrero and dates to circa 7000 BCE. Capsicum and potato originated in Andean Peru and date to 4000 BCE, while squash and gourd domestication occurred circa 9000 BCE based on evidence from southwestern Ecuador and Mexico, where the species were domesticated independently. *Cucurbita pepo* was also domesticated circa 2500 BCE in eastern North America. Domesticated sorghum dates to circa 5000 BCE and originated in Ethiopia, though it may have been domesticated in several centers in sub-Saharan Africa independently.

Foraging to Farming— The Neolithic Revolution

The term “Neolithic Revolution” refers to the marked change in lifeways from the stage of hunting and gathering to food production (i.e., plant cultivation and animal husbandry). The emergence of agriculture as sustained subsistence was neither accidental nor purely intentional. Instead, it resulted from the dynamic interplay of various factors, both external (i.e., relating to the conditions of environmental ecology) and internal (i.e., posing a challenge to human adaptive strategies).

Judging from the composition of the diet of those people who lived at the time of maximum glaciation during the last Ice Age, some 20,000 years ago, this period already included the protein-rich seeds of several of the wild plants in the Near East, among them species of wild grass and ember. It is from the experience with the taste of the seeds as foodstuff and their availability that hunter-gatherers began to experiment with them at a later period.

Human inventiveness was certainly spurred and the human mind challenged to collect seeds in greater quantity once they had ripened and to devise means to store them to prolong the span of time for consumption. It can be conjectured that the early experiments with wild seeds—for which the annual period of availability was always limited—were accompanied by simultaneous efforts to improve the capacities of their storage as foodstuffs. Experimenting with the seeds of wild plants is a necessary precondition for intentional plant cultivation.

The span of time from the first experiments with wild seeds to full-scale agriculture extends over 2,500 years, from circa 11,000 to circa 8500 BCE. Is it reasonable to describe the step-by-step evolution that is involved in terms of a revolution? The view of the modern observer who looks back into history tends to condense the proportions of absolute time, and longer periods may look, from the distance, more compacted than they really were.

The experiences of the hunter-gatherers with wild seed plants posed the challenge to remain in the area of their natural spread to follow the ripening and to engage in harvesting at the

➤ WAS THERE ONLY ONE NEOLITHIC REVOLUTION?

For many years, it was believed that the combination of technologies in the agrarian package is a prototype for all agrarian lifeways in the world. This belief made it easy to think of a spread of this prototype package from the Near East to other regions. However, the reality of what happened in the Neolithic Age is more complex and shows regional varieties of a transition from foraging of prehistoric hunter-gatherers to various forms of sustained subsistence. Recent findings in the archaeology of eastern Europe call for a revision of the idea of one single package of new technologies. The Neolithic Revolution produced at least two foundational packages of technological innovations: the agrarian package and the pastoral package. The agrarian package consisted of technological advances (in plant cultivation, animal husbandry, pottery, and weaving) characterized by sedentary lifeways, which made its first appearance in the Near East. The pastoral package consisted of technologies (the same as the agrarian package minus plant cultivation) characterized by semisedentary or nomadic lifeways, which made its first appearance in the East European steppe zone of the Pontic-Caspian region, extending between the Caspian Sea and the Black Sea in southern Russia.

What makes these new insights about an alternative package important is the evidence that

this package did not emerge as an offshoot of the agrarian package but rather as an independent form of subsistence. It was believed earlier that pastoralism and nomadism originated in regions where the crops from plant cultivation would have been too poor so that people living in those areas would have given up their sedentary lifestyle and would have focused on herding as the main form of subsistence.

The archaeological record of pastoralist culture in the steppe zone of southern Russia shows that herding developed in the region in the seventh millennium BCE, long before small-scale agriculture was introduced in the mid-sixth millennium BCE. Thus, the earliest variant of pastoralism did not originate as an offshoot of agriculture like nomadism in many parts of the world in later periods.

right time. This process of a seasonal presence of bands of hunter-gatherers in areas of optimal food supply furthered a development that was to become a major thrust in human socioeconomic evolution, the trend to adopt a sedentary lifeway.

Sedentism is a necessary precondition for the observation of the life cycle of wild plants and their seed production over a longer duration. Therefore, sedentism always precedes and predates the socioeconomy of plant cultivation. Sedentary lifeways enhance the transition to food production in the form of horticulture on a small scale and as agriculture on a larger scale.

When we speak of agriculture, we mean full-scale plant cultivation. The beginnings of this phase of food production date to circa 8500 BCE, and the earliest evidence for it comes from the Near East from the settlement of Jericho on

the west bank in the valley of the Jordan River. "Agriculture" is actually a blanket term for several forms of economic subsistence that are often interconnected. Those who practice agriculture also keep domesticated animals such as pigs, sheep, goats, and/or cattle. The production of food, of grain as well as meat, requires storage capacities (i.e., vessels to store food for later consumption). Therefore, the making of pottery unfolded, as a special technology, parallel to the other technologies.

In view of the network of technological skills that are involved, it becomes evident that when talking about agriculture, we are actually considering a diverse package of activities and technologies. Experts speak about the agrarian (or agricultural) package. In such contexts where the emergence of agriculture is referred

to—that is, to the three basic domains of plant cultivation, animal husbandry, and pottery and the related items—the agrarian package is defined as “the sum of traits that appear repeatedly in the Neolithic assemblages of Southwest Asia, Anatolia and Southeast Europe.”

The earliest signs of a trend toward sedentism are found in the ancient Near East, in the context of ecological changes that affected human living conditions. When the climate became colder during the Younger Dryas phase (in the course of the twelfth millennium BCE), this affected the availability of seeds of wild grass and other food crops. These food resources had been an important asset of nutrition for the hunter-gatherers of the region. In response to the ecological change, humans retreated to areas where wild grass was still available. In the vegetational refugia, humans adapted to local ecology and exploited the food resources intensively. The chain reaction of events during that phase of a shift from mobility to sedentism illustrates that the impulse for that development was sparked by ecological changes that in turn induced responses of human intentionality to cope with those changes.

Sedentism is a stable feature in any agrarian society. For reaching the stage of full-fledged agriculture, sedentary populations in the ancient Near East experienced a step-by-step transition. First is the sedentism of the Natufian people in the twelfth and eleventh millennia BCE (intensive exploitation of seeds of wild plants, beginnings of an intentional planting of wild seeds, no domesticated animals). Natufian settlements have been found at sites in Israel, Jordan, and Lebanon. Second is the sedentism of the early monument builders (at Göbekli Tepe, Çayönü, Nevalı Çori, and other sites in eastern Turkey) in the tenth and ninth millennia BCE (intensive exploitation of wild plants, intentional planting of wild seeds, no domesticated animals). Last is the sequence of sedentism of the early inhabitants of Jericho (ca. 10,000–8500 BCE, sedentary hunter-gatherers; ca. 8500–7300 BCE, domesticated plants; ca. 7300–6000 BCE, domesticated animals such as sheep and goats).

The history of sedentism and plant cultivation during the following millennia is the history of the spread of full-fledged agriculture and

animal husbandry in the area that has become known as the Fertile Crescent—extending from Egypt in the south over the Near East to Anatolia in the north and Mesopotamia in the east—and beyond. Those populations that founded the early civilizations of the Old World from the sixth to the fourth millennia BCE (i.e., the Danube civilization, Egypt, the city-states of ancient Sumer, and the kingdom of Elam in the Zagros Mountains) were agrarian communities.

Defining Domestication

The term domestication derives from the Latin *domus*, meaning “home.” It means the harnessing or taming of wild resources, notably plants and animals, for use by humans and involves some form of modification that distinguishes domesticated species from their wild relatives. Domestication was a momentous development and the first stage in the initiation of settled agriculture and the provision of food security. As a technology it irrevocably altered the relationship between people and the environment and underpinned global environmental and cultural history. It also facilitated wealth generation and human appropriation and alteration of the global carbon cycle.

WILD TO DOMESTICATED WHEAT

Wheat traditionally is regarded as one of the earliest domestic plants. It was introduced to human culture and to the productive economy on the territory of the Fertile Crescent as early as 9000–7000 BCE. Paleobotanic assemblages of the first settlements of Near East farmers indicate that it was cultivated together with barley, sometimes on the same plot of land. From the very beginning, early farmers explored several sorts of wheat, the most widespread among these representatives of tetraploid (emmer) and diploid (einkorn) wheats.

The identification of wild ancestors of wheat is complicated by the genetic diversity of wheat's domestic forms, which implies that they were introduced into farming independently. Einkorn (*Triticum monococcum*) is regarded as a relatively more archaic form in comparison with emmer; nevertheless, most paleobotanists believe that einkorn was domesticated in the Taurus region a little bit later than emmer on the basis of its more widely distributed wild form.

Emmer's wild form, which nowadays is growing freely in southwestern Turkey, western Iran, and Armenia, usually is regarded as not related to domestic emmer (*Triticum dicoccum* Schrank). This domestic variety instead is traditionally connected with the southern coarse-grained race

of tetraploid wild emmer, which was primarily domesticated in Palestine and then distributed all over the Near East.

The appearance and dissemination of soft types of wheat around 6000 BCE are traditionally associated with the process of natural hybridization of wild emmer and einkorn with their wild relative *Aegilops* in southern Iran and Transcaucasia. The wheat variant widely distributed in the Caspian region and Caucasus most probably resulted from the natural hybridization of emmer *Triticum dicoccum* Schrank or common (or bread) wheat *Triticum aestivum* and club *Triticum compactum*. It is worth mentioning that soft wheat managed to replace emmer only in Roman times.

The process of domestication begins with the selection of a wild species that is valued for a particular characteristic. Most species have been domesticated to provide food. In the case of plants the attraction might have been a high starch or sugar content, and in the case of animals it was edible protein. Other reasons for domestication include a capability for work or draft (e.g., ox and horse), assistance with hunting or herding wild or domesticated animals (e.g., dog), the provision of fiber (e.g., cotton and sheep), ornamental value (e.g., flowering plants), or as pets (e.g., dog and cat). There is a special relationship between domesticated species and humans, notably a degree of mutuality or symbiosis. This is sometimes expressed as the result of coevolution insofar as both humans and domesticated plants and animals have adapted to each other for survival.

The domestication of plants and animals is a comparatively recent development. The first domesticated species was the dog (*Canis lupus familiaris*) from the wolf probably about 15,000 years ago, though this is debatable. The place of first domestication is unknown, but as the earliest dates for sheep and cattle domestication circa 10,000 years ago come from the eastern Mediterranean region, it is possible that the dog was also first domesticated in that region. It is equally possible that the species was domesticated from the wolf in separate regions at different times. The period immediately after the last ice advance (i.e., 12,000 to 10,000 years ago) was a time of considerable innovation when numerous plant and animal species were domesticated and the first agricultural systems were initiated. This occurred in the eastern Mediterranean in the so-called Fertile Crescent and in southern China.

Emmer wheat (*Triticum turgidum*) and einkorn wheat (*Triticum monococcum*), barley (*Hordeum vulgare*), fig (*Ficus carica*), lentil (*Lens culinaris*), and chickpea (*Cicer arietinum*) were all domesticated in the Fertile Crescent between 9,000 and 11,000 years ago at about the same time as rice (the species *Oryza sativa*) was being domesticated in the middle Yangtze River valley. Nine thousand years ago corn (*Zea mays*) was being domesticated in what is now Mexico. Sheep, goats, cattle, and pigs were also domesticated in the Fertile Crescent between 10,500 and 9,000 years ago, and there was at least one further independent locus for cattle domestication in the Indus Valley of Pakistan, with a possible third locus in sub-Saharan Africa. Additional plant domestications occurred later in the Fertile Crescent, China, and Mexico as well as elsewhere. For example, potato (*Solanum tuberosum*) and tobacco (*Nicotiana* spp.) were domesticated in the Peruvian Andes, while domesticated squashes (*Cucurbita* spp.) and sunflower (*Helianthus annuus*) originated in central North America, and chicken and horse domestication occurred in Southeast Asia and the Eurasian steppes, respectively. From these centers of origin, domesticated species spread via migrants and trade to a wide hinterland.

How domestication occurs is open to question and varies between species. Domesticated plants are unlike their wild relatives because their life cycles and anatomy have been altered so that in many cases a plant may not be able to thrive and reproduce unless there is human intervention. In the case of animals there is a difference between domesticated and tamed. Tamed animals are taken from the wild and trained, while domesticated animals are bred in captivity and tamed. All domesticated species have been subject to selective breeding to accentuate desired traits, and thus their genetic characteristics have been altered when compared with their wild counterparts. In the process of such breeding other traits have been lost, and in many cases this means that the plant or animal cannot survive without human attention. Corn (maize) is a good example. It was domesticated in Mexico about 9,000 years ago from a wild grass called teosinte, which was selected because of its large seeds. Selective breeding over

thousands of years has produced modern hybrid varieties with larger seeds, but they cannot reproduce naturally through cross-pollination.

Given the many millions of plant, animal, and insect species that comprise the world's biodiversity, only a very small number have been domesticated. Even in today's high-technology world, the staple crops continue to be among those species that were first domesticated (i.e., wheat, rice, and maize). Similarly, the most numerous domesticated animals—sheep, pigs, cattle, and goats—were early domesticates, and relatively few animals have been domesticated when compared with plants. Why this is so is far from evident but possibly reflects the special characteristics needed for domestication and the special conditions that foster it. There is debate as to the roles of natural selection and selective breeding in domestication. Natural selection involves mutations that are independent of human intervention but render a proportion of plants and animals in a population more useful and easily manipulated by humans and are then selected by humans. Selective breeding over centuries has culminated in the high-yield crops and livestock that dominate world agriculture today. Moreover, selective breeding is becoming ever more precise through species manipulation at the molecular level using techniques of genetic modification, a major aspect of modern biotechnology.

Plant and Animal Domestication in the Ancient Near East

With the end of the last Ice Age came dramatic changes in global climate. Temperatures and precipitation increased in many parts of the world, and vast areas of land were opened as the glaciers retreated. Most plants, animals, and humans adjusted to these new conditions and even expanded into new regions. Around this same time, 10,000 years ago, groups of largely sedentary

hunter-gatherers living in the Near East started cultivating wild cereal grasses, such as wheat and barley. Within a few centuries the domestication of plants and animals was achieved. This new adaptation in subsistence acquisition was highly successful and soon spread to neighboring regions.

Domestication involves the human alteration of the genetic makeup of plants and animals to the point that they are no longer able to survive in the wild. The first domesticates appeared in the Fertile Crescent of the Near East, which stretches 1,242 miles (2,000 kilometers) from the Negev in Israel north through Lebanon, Syria, and southeastern Turkey and arches eastward to include Iraq and Iran. This region offered a hospitable environment with arable lands to grow crops. Moreover, wild cereals along with sheep, goats, pigs, and aurochs were native to the area.

The domestication process began with the selective harvesting and sowing of wild plants. As humans continued to choose the most desirable plants and seeds, changes in the succeeding populations began to emerge. Over time, the selected attributes of the plants became the norm, making distinguishing between wild and domesticated forms relatively easy. The same domestication process is essentially seen in animal populations as well.

Evidence of domestication can be seen in the archaeological record in the form of preserved macrobotanical remains and phytoliths (silica fossils) from plants. The seeds and phytoliths from domesticated forms of cereals, for example, are larger. The loss of anatomical features, such as the brittle rachis that distributes the seeds by natural agents, is also a sign of domestication. Although specialists cannot differentiate between wild and domesticated plant forms using pollen grains, a significant increase in a particular genus or species can point to agriculture. A spike in pollen grasses can denote deforestation to create agriculture fields as well as indicate the crops themselves. Future studies on plant DNA may also help clarify the origins of domestication.

Two species of wild wheat, einkorn (*Triticum monococcum*) and emmer (*Triticum dicoccum*), the latter of which is likely a natural hybrid of einkorn and goat grass, were domesti-

cated in the ancient Near East. Through selective harvesting and planting, these wild wheat forms eventually became domesticated varieties. The wheats can be distinguished on the basis of whether the husks or glumes stick to the seeds (domesticated) or are easily removed (wild). The wild forms are also known as naked or free-threshing wheats. Wheat forms that kept the seeds on the plant were able to be transported from the field to processing areas, a highly advantageous trait. Barley can be differentiated much the same way as wheats can, as their seeds are larger and the husks more robust. The number of rows of grain also changed. Two-rowed barley was domesticated into two-rowed hulled barley and eventually into six-rowed hulled barley. The latter domesticate increased the seed yield and chance of contributing grain to future plantings. Other domesticated plants include legumes (lentils, vetches, and peas), fruits (figs, apples, and pears) and nuts (acorns, almonds, and pistachios), all of which are larger.

Animal domestication occurred in the Near East shortly after plant domestication. Beginning with animal husbandry, wild animals were gathered, herded, and slaughtered for their meat. By 9,000 years ago people living in the Zargos region of the Fertile Crescent were managing captive goat herds. As humans selected out individual animals with advantageous traits for breeding, such as increased muscle content and docility, domesticated populations emerged. These goats were the earliest to be domesticated, followed by sheep, pigs, and cattle.

Based on teeth and bones found in the archaeological record, domestication is reflected by a number of morphological changes. The decreased size of the domesticated form of the animal is apparent in several species, as is the reduction in jaw size and the increased crowding of teeth. The shapes of the horns of goats and sheep are indicative features as well. Certain pathologies can also show animal domestication because using trained animals as beasts of burden can inflict osteoporosis and other bone deformities. Overcrowding and unclean pens can lead to diseases as well. Although less likely to be preserved, the wool and hair in the skins of domesticated animals are also different.

Supporting evidence of domestication can also come from the faunal assemblages as a whole. Cattle bones reflecting the slaughtering of young males and older females, for example, point to farming practices in which the females are kept alive longer for breeding and dairy products. The presence of animal species outside their natural habitats also reflects domestication, as does artifact evidence including plows, yolks, and pens.

It is now clear that domestication first emerged in areas with an abundance of resources such as the Fertile Crescent, where the risks of exploring new subsistence strategies were less. It is also apparent that agriculture initially appeared among more sedentary and complex groups of hunter-gatherers, such as the Natufians living in the Levant, and was accompanied by a shift in the economic organization of these populations. The farming lifestyle required people to stay in one place in order to tend the fields. This significant change in lifestyle also led to new innovations such as ceramic production, which allowed for the storage of harvested crops.

By 8,000 years ago domesticated plants and animals were firmly established in the Near East. They then spread into Europe and the Nile Valley through the diffusion of ideas and products. Agriculture was quickly adopted in areas where hunter-gatherer groups occupied all the inhabitable ecozones and populations were large enough to support the process. Other regions, including Japan, China, the Americas, and the southern margins of the Sahara in Africa, also witnessed the domestication of plants and animals although independently from the Near Eastern farmers.

Plant Cultivation and Animal Use in the Nile Valley

The Nile Valley was characterized by diverse habitats at the end of the last Ice Age. Marshlands supported varied wildlife, which in turn supported hunter-gatherers who established camps along the Nile's length. They exploited fish, water and migratory birds, and game, including aurochs, hartebeest, and gazelle, as well as plant species such as sedges and grasses, including the tubers of *Cyperus* sedges, which were extracted with digging sticks. However, despite abundant food, life was precarious given the unpredictability of Nile floods and their often dramatic impact on the floodplain and delta. Toward the beginning of the Holocene, these hunter-gatherers became increasingly sedentary. The Qadan culture, from the central Nile Valley, is one such example that existed circa 15,000 to 11,000 years ago. They buried their dead in cemeteries, had a tool kit of microliths, and a range of grinding implements. They are considered to be the precursors of the first agriculturalists in the Nile Valley.

How agriculture developed in this region is debatable. Were plants and animals domesticated in situ, or were they introduced from the Levant/Middle East? How, by whom, and when domesticated species were introduced remains unknown, but as in the Levant/Middle East, the use of such species spread rapidly. Evidence is limited, mainly because silt deposition has buried ancient villages, but the general consensus favors an introduction of domesticated species by circa 8,000 years ago. The earliest date for the presence of domesticated crops is circa 7,200 years ago and is from the El-Badari settlements in Upper Egypt, while one of the earliest dates for domesticated animals, notably goat, is circa 6,600 years ago from Napta Playa, 62 miles (100 kilometers) west of Abu Simbel in the Western Desert. This is considered to be the oldest Neolithic site in Egypt and was constructed when dry savanna was still characterized by prevalent vegetation prior to the development of drier desert conditions. Remains of six-rowed barley have also been found at this site along with pottery and numerous groups of monoliths

carved from sandstone. Glimpses of lifeways and deathways during the late Neolithic are also afforded by excavations at the Gebel Ramlah Playa, 80 miles (130 kilometers) west of Abu Simbel. Here communities of pastoralists herded aurochs, which may have been domesticated in situ, as well as goats and sheep. The animals were herded to take advantage of seasonal grass growth in what was then still savanna, and as the herders moved on they left behind hearths. These communities buried their dead in cemeteries, either as single or multiple burials, circa 6,000 years ago. The graves were rich in grave goods, including stone tools, pottery, palettes, polished pebbles, and jewelry. Vessels known as tulip beakers decorated with incised and stippled patterns were used specifically as grave goods, while the palettes were made of ivory, horn, pottery, or sandstone and contained cosmetics of various colors, which were derived from a range of mineral sources. The jewelry was varied and well crafted. It included necklaces, pendants, and bracelets made from a range of materials such as agates, turquoise, carnelian, various shells, bone, and horn. Bone needles and daggers as well as flint knives and arrowheads were present. These artifacts indicate division of labor within society and a material culture that embraced decoration. One grave contained a sheet of mica on which a tilapia fish had been carved. The fact that stones such as cornelian and shells from the Red Sea coast were present indicates well-developed trade with other regions.

By 6,000 years ago drought conditions were increasing, which may have resulted in human communities moving closer to the Nile to ensure a water supply and to adopt domesticated plants and animals to ensure a food supply at an environmentally precarious time. By this time, settlements associated with farming were in existence. Many of these are associated with the Badarian culture, named after El-Badari on the east bank of the Nile near Assyut in Upper Egypt, dated to circa 7,200 to 5,000 years ago. Here there are the remains of approximately 40 settlements that were permanently occupied, and there are also many cemeteries. The settlements consisted of mud-brick houses with hearths and had large granary pits for barley and emmer wheat. These cereals were also found in graves that reflected

considerable attention to body burial, including the use of linen shrouds and the burial of women with plaited hair and ivory combs. The flax to produce the linen was grown locally, and weaving was well established. Distinctive figures carved from hippopotamus ivory were also placed in graves. Tools included end scrapers, perforators, axes, bifacial sickles, and arrowheads. The remains of domesticated cereals and domesticated animals, which included cattle and sheep, indicate a mixed farming economy. Dogs, the earliest domesticated animal dating to at least 12,000 years ago, were also kept, and most were probably used for herding rather than as a source of food. Fishing and hunting were additional sources of protein. The Badarians used a particular style of pottery with a rippled surface. They also mined malachite, a copper mineral prized for its bright green color that was ground up to produce a green base for cosmetic purposes. The Badarian culture is also associated with early metalworking, notably copper for the fashioning of pins.

Merimde Beni Salama, contemporaneous with the Badarian, also provides evidence for early agriculture. Remains of this settlement are located on the edge of the Nile Delta and have an area of approximately 49 acres (20 hectares). It consisted of a cluster of mud-covered houses, sometimes oval shaped and constructed half belowground and half aboveground with hearths. The mud blocks contained straw for binding, and roofs were made with reeds or rushes. Storage jars and storage pits were used for grain and water. The major food types were wheat and barley, and cattle, goats, and pigs were kept. Estimates suggest that the village was occupied by between 1,000 and 2,000 people. Cemeteries were located outside the village borders, and bone assemblages imply that cattle and sheep were used for sacrifices.

The cultures described above were the precursors of the dynastic Egyptians (pharaohs) who controlled the Nile Valley, built monuments such as the pyramids, and entombed their dead with a wealth of grave goods.

Plant and Animal Domestication in East Asia

The transition from economic subsistence based on foraging (i.e., hunting and gathering) to plant cultivation (i.e., horticulture and agriculture) is a major process of the postglacial period that resulted in fundamental changes of the lifeways of those populations that were involved. During the transitional period, people became sedentary and started to experiment with the seeds of wild plants, selecting the most nutritious for intense use. This then led to more extensive intentional use of such seeds for growing crops. Systematic plant production—that is, full-fledged agriculture—was the result of more than 2,000 years of experimenting in the Near East, and in other parts of the world where agriculture emerged independently, it also took a longer span of time for plant production to become the main system of subsistence. The emergence of agriculture has been celebrated as the Neolithic Revolution. A closer inspection of the conditions of the incubation phase reveals the relativity of the concept “revolution.”

The earliest evidence for the transition to the Neolithic in human history comes from the Near East and dates to the eleventh millennium BCE, with full-fledged agriculture appearing around 8500 BCE (the Neolithic Revolution). All other instances of early agriculture in the world are younger. Based on recent archaeobiological findings in East Asia, it is possible to relate the early experiments with wild rice to the seventh millennium BCE. In the Near East, the early date for experiments with domestication may be explained by exceptionally favorable conditions, set by a unique combination of ecologically adaptable and nutritionally complementary domestic plants and animals. In East Asia, this process did not yield the same kind of balance as in the Near East. It seems that in the Far East, plant domestication had priority over animal domestication.

➤ BASHIDANG (CHINA)—EARLY RICE CULTIVATORS

The Neolithic settlement of Bashidang extends over some seven acres or three hectares and is located in the middle Yangtze drainage. The lowest layer of human occupation dates to the eighth millennium BCE. Pottery, made of clay tempered with rice chaff, was introduced at the beginning of the seventh millennium BCE. The villagers constructed pile dwellings, and they buried their dead together with pots and stone ornaments. The inhabitants of Bashidang lived in a community sustained by the cultivation of rice. Evidence has been provided by an analysis of the remains of rice spikelets with marks that reveal that they were intentionally torn off the stalk (e.g., by threshing). In addition to rice, the remains of other plants—namely water caltrop and lotus—were found that are typical of wetlands such as marshes and lakes. The people probably already kept livestock, but this is as yet unconfirmed by the bone remains. The layout of Bashidang and the lifeways of the villagers that can be reconstructed from the material remains resemble those at Pengtoushan, situated some 12.4 miles (20 kilometers) to the southeast.

—Harald Haarmann

There is consensus that the earliest evidence for the domestication of plants in East Asia comes from central China, although there is still much debate about the location of the first self-sufficient communities. Although the period immediately following the end of the last Ice Age and the melting of the Eurasian ice shield saw a moderately warm climate, there was another intermediate period of cold weather that lasted to about 8000 BCE (called the Younger Dryas period). Another period of warming followed that and brought subtropical vegetation and fauna into the Yangtze Valley. Among the plants that spread from refugia was wild rice, and it is with this plant that Neolithic people came to experiment first. Rice was to become the major domesticate for food production in East and Southeast Asia.

Several archaeological sites in the middle and lower reaches of the Yangtze Valley (Pengtoushan, Bashidang, Fenshanbao, Tianluoshan, and other sites) and the Huanghe (Yellow River) valley (Erlitou) have yielded significant data as

proof of the Neolithic transition. The process of transition in the Far East was more complex than in the Near East. The main reasons for this were differences between climatic and vegetational zones in China where plant cultivation started out, which in turn explains the variety of plants with which people in East Asia experimented for the purpose of domestication. In the area of primary transition to agriculture—that is, in the area from which agriculture later spread into other regions—a southern and a northern gravitation can be discerned, each with individual species of domesticates.

The southern area of plant and animal domestication (warm-temperate Yangtze Valley):

Plant domesticate: rice (*Oryza sativa*)

Domesticated animals: dog, pig, chicken, water buffalo

Technology: pottery, utensils for agriculture, stone axes

Lifeways: grain-livestock farming; diet including wild plants

The northern area of plant and animal domestication (cool-temperate Huanghe Valley):

Plant domesticates: broomcorn, foxtail millet

Domesticated animals: dog, pig, probably also chicken

Lifeways: mixed economy (i.e., hunting, fishing, plant cultivation)

The origins of the cultivation of soybean—well known from historical times—cannot yet be dated with any certainty. If this plant was not part of the diet of Neolithic peoples and if goats and sheep were not among the domesticates in China, then the suite of East Asian domesticates was not as wide as that found in the Near East.

The domestication of rice was a prolonged process. At Tianluoshan (south of Shanghai) the remains of rice spikelets, belonging to archaeological strata of the fifth millennium BCE, have been found, belonging both to wild plants and to domesticates. The amount of rice that the people of Tianluoshan consumed increased over a span of several hundred years but was still only a quarter of the total plant diet by circa 4600 BCE. There was a steady increase of domesticated rice and a decrease in the consumption of wild rice, but the development was slow.

The spread of rice cultivation from the Yangtze Valley to other regions of East Asia was a prolonged process also. In China, the thrust of the spread of agriculture was mainly directed from north to south, crossing the boundaries of different climatic zones, and this set demands for complex ecological adaptations. The earliest traces of rice cultivation in mainland Southeast Asia date to circa 3700 BCE. During the third millennium BCE, rice production increased especially in Vietnam and Thailand. The spread along latitudinal zones was less vigorous. Rice cultivation reached Korea toward the end of the second millennium BCE, and in Japan the systematic cultivation of rice began as late as the fourth century BCE.

Early Food Producers in the Indus Valley

The Indus Civilization represents one of the four ancient protohistoric urban cultures in the world, the other three being located in valleys of the Nile (Egypt), the Tigris-Euphrates (Iraq), and the Ho (China). The first-known site, Harappa, was discovered in the 1820s in modern-day Pakistan. Subsequent exploration revealed sites distributed in association with the Indus River and

➤ MEHRGARH

Mehrgarh, located on the Kachi Plain of Baluchistan, represents the earliest evidence of plant and animal domestication in the Indian subcontinent. Its cultural roots originate in West Asia, from which Neolithic groups dispersed into other regions. Occupational levels start at about 6500 BCE, when farmers cultivated and exploited wheat, barley, peas, cotton, dates, and sesame seeds and raised cattle, sheep, and goats. Divided into seven periods of development, the earliest does not contain any pottery, which seems to appear at about 5500 BCE at the site. The next two periods are Neolithic with ceramics, and the last four can be attributed to the Chalcolithic phase with an increase in specialized artifact production. Houses were made of mud bricks, and different types of artifacts have been recovered: ornaments of bead, shell, and turquoise (representing long-distance transport), terra-cotta and bone seals, stone and copper drills, stone sickle blades in bitumen, bone points, awls, stone blades, kilns, and crucibles for melting copper. Flexed burials have been found

Ruins of an ancient mud-brick village, dating from before 6500 BCE, Mehrgarh, Pakistan. (Corbis)

here with ochre, grave goods (e.g., ornaments, ground axes, baskets), and animal bones. The site represents one of the earliest that had a direct influence on the subsequent birth and maturation of the Indus Civilization.

—Parth Chauhan

its tributaries, including southern and western Pakistan as well as hundreds of sites in north-western India (Rajasthan and Gujarat). A few sites are also located in the periphery zone such as Jammu and Afghanistan (Shortughai). Hundreds of settlements of different types (e.g., city, trading post, artifact factory site, rural satellite site) are located on the river floodplains in fertile zones containing thick deposits of rich alluvium (except in Saurashtra), on islands, in coastal zones, and in lakeside contexts. Since a large number of sites are associated with the ancient Saraswati River (no longer extant) in Rajasthan, some scholars have argued for changing the name to the Indus-Saraswati or Saraswati-Sindhu civilization. Nonetheless, it is clear that the roots of this culture are located in Pakistan, primarily represented by such sites as Mehrgarh.

The Indus Civilization is divided into four developmental phases: Pre-Harappan, Early Harappan, Mature Harappan, and Late Harappan. The earliest food-producing phase spans 5500–3300 BCE and represents the Neolithic and pastoral roots of the earliest Harappan evidence. This is

followed by a Regionalization Era or the Early Harappan phase (3300–2600 BCE), an Integration Era or the Mature Harappan phase (2600–1900 BCE), and the Localization Era or the Late Harappan period (1900–1300 or 1000 BCE). These phases are further divided into various subphases (e.g., Hakra, Harappan 3B) based on data from different sites (e.g., Mehrgarh, Kot Diji, Nausharo, Harappa) and associated strata.

The cultural identity of the Harappan Civilization is essentially defined by the uniformity in its architecture, artifacts, script, and symbols and motifs illustrating various levels of technological and cultural sophistication. The distribution of raw materials for artifact manufacture was facilitated by an extensive maritime trade network with Mesopotamia. In fact, the term “Meluhha” in Sumerian literature may refer to the Harappan culture. Raw materials such as chert, lapis lazuli, shell, ivory, precious stones, limestone, faience, and copper were sought in different regions. Earlier research hinted at the introduction of plant domestication to the Harappan culture; this was later refuted as new evidence confirmed an

indigenous development of food production. The primary evidence of this comes from Mehrgarh as early as 6500 BCE. Many sites have also yielded the bones of domesticated animals (e.g., zebu cattle, water buffalo, goat, sheep), and at Kalibangan, plowing patterns, inferred from modern analogs, have been preserved.

The majority of Harappan sites are only a few thousand square feet (a few hundred square meters) in size, and some of the largest ones are Harappa, Mohenjo-Daro, Rakhigarhi, and Dholavira, probably being urban administrative centers. Some of these sites are surrounded by large fortification structures, and coupled with the context and configuration of some human burials at Mohenjo-Daro, the Harappan culture was long embroiled in controversial debates regarding the Aryan invasion theory, now theoretically defunct. The fortifications may have served as protection from seasonal floods, since many such sites are located within major floodplains. These structures were supplemented by large platforms made from mud bricks that were standardized in their dimension (ratio of 4:2:1) across the Harappan domain. In most cities, the streets ran in north-south and east-west directions, and many had covered drains. Houses were often two stories and contained courtyards, and water was generally obtained from wells. Other unique structures included large granaries, gates, and the Great Bath at Mohenjo-Daro, which may have been for public or ritual bathing. The lack of palaces and temples points to an egalitarian society of traders, farmers, artisans, and other occupations.

Some of the large and medium-sized sites are generally represented by large mounds variably covering human burials, brick structures, hearths, kilns, and associated material such as burnt bones, pottery fragments, and a large variety of other artifacts made from steatite, carnelian, agate, gold, copper, silver, and bronze. Many artifacts, especially pottery designs, exhibited regional styles and symbolic patterns. Some forms of art include a statue of a priest-king, a bronze statue of a dancing girl, and a terra-cotta figurine of a female with a headdress. From the numerous female figurines, it has been argued that these people worshipped a mother-goddess.

Other items include toys, ornaments, beads, and bangles, some of which were utilized as grave goods. Stone cubes of various sizes were used as weights, with precise measurements graduated at a uniform rate. Gradual but distinct transformations in the architecture and artifacts are visible over time. One of the most fascinating aspects of this culture is its script, mostly found on small seals of steatite, that remains undeciphered despite over a century of research. However, we do know that the script was read from right to left. This evidence appears indigenously in the region at about 2500 BCE, and the largest evidence is a public sign from Dholavira. The seals depict over 400 individual symbols (e.g., trees, animals, horned deities, people, and a mythical unicorn-like creature). One cross-legged anthropomorphic figure is likened to Pashupati or Lord Shiva, the Hindu god of destruction.

By about 1900 BCE many cities and towns were abandoned, although some cultural elements persisted or dispersed into other nearby regions. A combination of multiple factors rather than one dominant factor contributed to the decline of the Indus Civilization. This decline included a geographic shift south and southeast to the Indo-Gangetic plains and was a result of the drying up of major rivers (e.g., Saraswati) and changing patterns of climate. This subsequently led to the collapse of the prominent trade network with Mesopotamia. Distinct regional cultures also developed soon after 1700 BCE (e.g., Cemetery H Culture). The continuity of Harappan material culture up to the modern day is reflected in pottery designs, bullock carts, and fishing boats.

Early Horticulture in Melanesia

Horticulture began in Melanesia at least 10,000 years ago and perhaps much earlier. Outlined here is a description of Melanesian horticulture and the plants involved, setting a framework for research. Methods involved use microscopic research and proxy data within a conceptual framework sympathetic to very long-term human involvement with food plants.

Today, crops in Melanesia are grown in gardens, not fields. That is, most are small-scale and consist of a mix of plants grown for food, condiments, decoration, and medicine. They are cultivated with wooden hand tools such as spades and digging sticks rather than with plows. Most gardens are short-lived, cleared and planted for a few years only. They are fenced only when predators, such as feral pigs, may be a problem.

► KUK SWAMP

Kuk Swamp is in a low-lying part of the Wahgi Valley, in the Central Highlands of Papua New Guinea. Archaeological excavations on this site over the last 30 years have revealed six phases of horticultural systems, the oldest dating to about 10,000 years ago. The systems indicate increasing complexity with time.

Phase 1 consists of some rather indistinct and irregular mound and basin ancient ground surfaces possibly draining into a humanly modified natural stream channel. Stake holes, postholes, pits, and other clearly artificial cuttings show that the paleo-surfaces were humanly created. The presence of *Colocasia* (taro) starch grains on stone tools and *Musa* phytoliths in the soil confirm that humans both planted and modified the land. A thick clay fan, deposited from around 9,000 years ago, indicates that soil washed away after land clearance.

Phase 2 begins about 6,900 years ago. Its ancient surfaces comprise interconnected networks of depressions and small channels that outline roughly circular raised areas about 3 feet (1 meter) across. Large drainage channels exist at a similar stratigraphic level and are inferred to have been drainage for excess water. The system seems designed for growing a range of plants: wetter areas for *Colocasia* taro and the mounds for less water-tolerant sugarcane, bananas, and green vegetables. Remains of some of these have been found both in features and as residues on tools.

The organization of Phase 3, circa 4,800–2,300 years ago, is quite different. It displays a network of rectilinear ditches meeting each other at right angles and clearly articulating into large hand-dug drainage channels, which are up to 0.31 miles (0.5 kilometers) long. Several other sites in the Wahgi

and elsewhere in the Highlands, dated to the same period, provide similar evidence. Pollen, charcoal, and rates of change in these are further proxy evidence for humanly caused environmental alteration. Wooden artifacts associated with these systems include a long paddle-shaped wooden spade dated to 4,200 years ago, exactly similar to spades used throughout the Highlands in the early twentieth century, as well as digging sticks.

Later phases continue the same pattern of grid systems, which become gradually tighter-patterned as the swamp became wetter. In Phase 6, the last phase, sweet potato, a New World import, was grown on the mounds. This is also the only time period for which house remains have been found in the swamp area.

Melanesian crops are nearly all roots and fruits, with starch from sago tree (*Metroxylon sagu*) pith a notable exception. Common root crops include various forms of taro (*Colocasia* spp., *Xanthosoma* spp., *Alocasia* spp., and *Cyrtosperma* spp.) and yams (*Dioscorea* spp.); sweet potato (*Ipomoea batatas*), of American origin, was added about four centuries ago. Tree crops include bananas (Musaceae), breadfruit (*Artocarpus altilis*), canarium, and pandanus. Sugarcane (*Saccharum officinarum*) is common, as are many varieties of green vegetables. Genetic studies have demonstrated that many of these plants, including some taros, yams, and bananas, are endemic to the region and are likely to have been first taken into cultivation here.

Understanding current Melanesian horticulture suggests how the search for earlier forms needs to proceed. The plants involved do not have hard skins or seeds, unlike the wheat, millet, or maize cultivated elsewhere. Many do not produce pollen or do so in very limited quantities. What they leave as relics are microscopic starch grains and phytoliths (opalised plant cells). These can be found on stone tools used for processing plants as well as in soil samples from gardens and village sites. Their extraction is laborious and their identification rarely easy, but they are the only precise avenues to plants of the past. In most cases, however, these methods do not distinguish between cultivated and wild plants.

Another avenue to understanding plant use comes in the microscopic use wear that any use creates on the edges of stone tools. This can separate, for example, scraping from cutting, useful for confirming the ways plants were processed.

Proxy data is required to infer that prehistoric plants were cultivated rather than collected in the wild. The most common of these are changes observed in paleoenvironmental records such as increases in charcoal, implying local firing of cleared areas; pollen of early colonizer plants; geomorphic changes showing increased soil runoff as the result of clearance; and changes in the proportions of animal species hunted. Much less common is the evidence of structured facilities such as drains and terraces, occasionally associated with appropriate tools. It is the conjunction of many of these lines

of evidence that makes the Kuk Swamp site so important.

The earliest evidence for the human use of plants that are grown in present-day gardens occurs in Kilu cave on Buka Island. Starch grains of the genus *Colocasia* sp. (probably taro) on 14 small flake tools and of *Alocasia* spp., a similar plant, on 3 others also provide evidence. These and other tools also displayed use polish on sharp edges and can be inferred to have cut and scraped taro before cooking.

But were these plants grown in gardens? This is uncertain, because taro is native to the island, and no other kinds of evidence were found. While these roots may simply have been gathered from a local swamp, most researchers believe that some curation is likely. Curation, or caring for plots in the form of weed removal and increasing sunlight to naturally growing plants, is quite frequent throughout Melanesia. Nowadays, it is applied especially to forest trees with edible fruits, such as canarium and many varieties of pandanus. A more complex form of curation occurs with sago palm. Found now in localities where they would not naturally occur, these large stands are the result of people moving young plants and allowing them to grow. These plants are not domesticated in any visible way, nor are they fenced off, so they appear to be wild even though each stand is owned and harvested.

Determining when formally bounded gardens were established and plants were domesticated is difficult in Melanesia. Apart from the Highlands of New Guinea, proxy data of the kinds outlined above is almost nonexistent before about 1500 BCE. At that time, the arrival of pottery allows village areas to be identified, and geomorphic and pollen data show land clearance. There are, however, sufficient hints to show that horticulture in Melanesia began at least 10,000 years ago, while some form of gardening may have started long before.

The Spread of Agriculture into Europe

Agriculture was initiated in several different regions and at different times during the 12,000 years since the last Ice Age ended. These regions were the Near East or Fertile Crescent, the lower Yangtze Valley in China, Mexico, the Peruvian Andes, sub-Saharan Africa, and the eastern United States. Developments in the Fertile Crescent were the major influences on the crops and livestock that spread into Europe between circa 10,000 and 5,000 years ago. During this period, hunter-gatherer communities were transformed into farming communities, though both hunting and gathering continued to supplement agriculture. It was not until circa 1500 CE that major additions to Europe's food sources occurred as a result of exploration of the New World and trade with the Far East.

The first crops to be domesticated were emmer and einkorn wheat; barley; various legumes such as the lentil and chickpea, which are often referred to as founder crops; and the fig. These were selected because they had been valued as food in the wild and proved to be amenable to selection. Similarly, sheep, cattle, goats, and pigs were domesticated from native animals. It is also possible that the dog was domesticated in this region, at least 15,000 years ago, to assist with the herding and hunting of wild animals. Other domesticates included rye, pea, and faba bean. All of these species were introduced into Europe, and only rarely were new crops added to this complex. The ramifications of this spread were profound. Landscapes and cultures were transformed as settled rather than nomadic lifestyles developed and as Europe's forests began to give way to arable fields and pasture.

How this occurred is a matter of debate, and there is no reason to suppose that the same process occurred throughout Europe over the 5,000

➤ CARDIAL CERAMICS

Early Neolithic ceramics are traditionally seen as those decorated with stamps. In the case of Cardial ceramics the serrated edge of hearth-shaped *Cardium edule* shells were used as a stamp for soft clay decoration. Traditionally, it is regarded as the earliest type of pottery discovered in the southern part of western Europe and dated to the seventh through fifth millennia BCE.

Cardial ceramics were widely distributed along the central and western coasts of the Mediterranean region, including Corsica, Sardinia, the Mediterranean part of Spain, southern France (Provence), and Liguria. The best-known sites with Cardial ceramics are Arene Candide in Italy and Shateaneuf-les-Martigues in France. Rarely are ceramics decorated with stamps of *Cardium* mollusks discovered outside the Mediterranean region.

Domestic cattle breeding was already familiar to Cardial ceramic creators. They used domestic large cattle, pig, and sheep, and they also practiced plant domestication.

The Cardial ceramic culture is relatively simple and is represented by rough, ball-shaped pots; pots with rounded bottoms; and pots with tubular drains. In some cases Cardial ware is finer than so-called epi-cardial or Roucadour-type ceramics found in the western Mediterranean and in Atlantic France. On this base it was supposed that Cardial ceramics were used as items of prestige exchange.

Zilhão, J. "Radiocarbon Evidence for Maritime Pioneer Colonization at the Origins of Farming in West Mediterranean Europe." *Proceedings of the National Academy of Sciences of the United States of America* 98(24) (2001): 14180–14185.

years that it took for agriculture to spread as far west as Britain or as far north as Scandinavia. There are two major theories: cultural diffusion and demic diffusion. Cultural diffusion involves the dissemination of ideas and their adoption by existing hunter-gatherer groups whose social organization was consequently transformed. This diffusion may have been linked with trade such as that associated with obsidian, which was well established by 12,000 BCE and involved the

exploitation of obsidian in Anatolia and Cappadocia. Other traded goods included semiprecious stones, stone for ax manufacture, stone implements, and pottery. These were exchanged for hides and crops, which ostensibly introduced domesticated crops and livestock beyond their region of origin. In contrast, demic diffusion involved the migration of farming people, initially from the Fertile Crescent, who merged with or displaced hunter-gatherer groups gradually throughout Europe. Evidence for cultural diffusion derives mainly from the archaeological record, which includes plant remains (archaeobotany) in cultural contexts and artifacts, especially pottery, that reflect innovation and contact between different human groups. This record, which is open to interpretation, is compiled in association with age-estimation techniques such as radiocarbon dating to produce a chronology of the spread of agriculture. Moreover, investigations of the present-day genetic constitution of Europeans have been undertaken to establish the relative importance of demic diffusion since it is considered that persistent migration into Europe would be reflected in the incidence of specific gene markers.

Contact between groups is reflected in the spread of pottery, notably a distinct banded pottery known as linear Bandkeramik in German (also known as LBK) as well as other artifacts and building structures that were widespread in Europe. While this commonality reflects common influence, it cannot be determined if cultural or demic diffusion occurred. Other lines of evidence more directly indicate directions and timings of the adoption of agriculture. For example, cereal grains in dated archaeological deposits indicate that the dissemination of cereal cultivation was initially quite rapid, taking some 3,500 years to spread from the Fertile Crescent along the eastern Mediterranean coast to the Iberian Peninsula. However, the pattern of spread into northern Europe appears to have been slower and sporadic. Following establishment in the Balkan region circa 8,000 years ago, there was a hiatus of circa 800 years before a surge north. Such a pattern can be interpreted in terms of rapid spread along the Mediterranean coastal region facilitated by sea connections and a relatively uniform climate similar to that of the Fertile Crescent, making

crop cultivation straightforward. In contrast, the spread north and northwest would have been more difficult given mountain barriers and dense forest plus climatic differences to which new crops would have to adapt. It is equally possible that hunter-gatherer communities were thriving under a subsistent lifestyle; either or both factors could have created inertia until innovation became essential.

The development of genetic (notably DNA) research has had considerable implications for archaeology as it has had for forensic science. The fundamental role of DNA relates to heredity and the legacy it leaves in modern populations. For example, if demic diffusion was responsible for the spread of agriculture, gene markers characteristic of the Fertile Crescent would be abundant throughout Europe.

A study reported in late 2008, based on DNA inherited through the paternal line of more than 1,000 men living in southeastern Europe, showed that the majority of male genetic groups predate the shift to agriculture and reflect the expansion of human populations after the last Ice Age. A degree of demic diffusion is indicated in the eastern Mediterranean basin, but otherwise the genetic evidence supports cultural diffusion as the dominant mode of transfer for the spread of agriculture in Europe.

The Hunters and Gatherers of Sub-Saharan Africa

The hunter-gatherers of sub-Saharan Africa were people who subsisted on wild animals and plants, in contrast to settled Neolithic farmers or

pastoralists supported by domesticated plants and animals. Generally, the hunting and gathering societies worldwide evolved before the beginning of domestication of plants and animals. The hunter-gatherers lived in small bands and exploited the resources available to them. They were also generally believed not to have a permanent base, as their movement was dictated by the availability of food and game.

The hunters and gatherers of Holocene Africa displayed a wide variety of adaptations to their environments. The Holocene epoch is a geological period that began approximately 11,550 calendar years BP (about 9600 BCE) and continues to the present. The Holocene is part of the Neogene and Quaternary periods. During this period areas with dense forest such as western Nigeria were not easily exploited, as human groups often chose to settle within breaks in the forest beside lakes and rivers, where freshwater fish and water fowl as well as game animals were available.

Many of the assemblages of these African hunters and gatherers were dominated by a microlithic stone tool technology. Microliths consist of tiny blades and flakes of stone, of which one end was backed with a blunting retouch to make them easier to handle or to mount into mastic or with glue in a composite tool. These are small bladelets or segments of blades and flakes often but not always geometric in shape that have been blunted by retouch along one or more edges, the blunted part being opposed to a sharp cutting edge. The standardized flake is used to make composite tools with flint or chert cutting edges inserted into wooden or bone hafts. The blunting facilitates hafting, and several of the segments might be mounted by setting them in mastic to form a composite tool or weapon. The microliths were used in various combinations such as for the barbs on a multi-barbed spear, the heads of arrows, or the blades of knives, sickles, or saws.

The raw materials used for this technology in Africa were quartz and other fine-grained rocks. Microliths are indicative of a more efficient use of stone and of an intensified exploitation of the environment. Some of these microliths, for instance, were used as arrow barbs, and thus they mark the appearance in certain areas of the bow

Triple burial from a site in Gobero, Niger, about 5300 BCE. An adult female and two small children are buried with legs and arms entwined. Pollen found beneath the skeletons indicate the bodies had been laid on flowers, and the burial also contained four arrowheads. (AP Photo/Mike Hettwer, National Geographic Society)

and arrow, which indicates an emphasis on hunting. The microliths industry perhaps represents the culmination of a development in stoneworking that had its origin right from the Acheulian period. Microliths dating to at least 30,000 years ago have been found at Matupi cave in eastern Democratic Congo. At the mouth of the Klasies River in South Africa the microliths industry has been dated to 70,000–60,000 years ago, making it one of the earliest instances of stone industry in the world. In the southern African region hunter-gatherers are best known archaeologically from the varied complex of stone industries known as the Wilton, dating from about 6000 BCE onward in which microliths played an important part.

Other substantial archaeological evidence for these people includes organic remains from dry cave deposits in southernmost Africa, such

as at Melkhoutboom cave, and from waterlogged sites such as Gwisho hot springs in southern Zambia. Based on this evidence, archaeologists are of the opinion that the hunter-gatherers apparently made use of wood for bows, arrows, digging sticks, pegs, and wedges. It has also been suggested that hunter-gatherers would have probably made bark into trays and sewn leather into bags and clothing. It has been documented that plants were an important source of food for the hunter-gatherers, though they also made use of plants for other purposes, such as medicinal.

The economic life of the hunter-gatherers consisted of gathering plant foods with stone reaping knives or digging up tubers with digging sticks and hunting with spears and the bow. They exploited resources by moving around their landscapes generally in small groups, occasionally coming together in a larger seasonal gathering. They were characterized by mobility, they probably maintained a complex network of kinship links, and their societies were essentially small-scale in nature. The geographical and seasonal distribution of resources dictated the size and dispersion of these human communities and set a limit to their numbers. The hunter-gatherers could not produce their food requirements, so they were usually not many in number. In most cases they moved about in bands seasonally. Once the food resources at a particular geographical location were exhausted, they moved on to other locations where their needs could be met.

The community and social organization of the hunter-gatherers has been adequately reconstructed from plant remains and other cultural materials recovered in connection with the group. Plant remains along with animal bones have thrown light on the seasonal movement of settlements of the group. For instance, groups in the southwestern Cape moved regularly between the coast in winter and inland areas in summer. It seems likely that seasonal movement included gatherings of people at resource-rich times of the year when commodities could be exchanged and social relationships reinforced, and they dispersed at other times when resources were more limited. Also, bored stones that occur in some of the lithic assemblages ap-

pear to have served as digging stick weights to facilitate the exploitation of plant food. The dead were buried accompanied by tools, personal ornaments, and other items, sometimes including painted stones, perhaps indicating a belief of life after death. Personal adornment was common and included beads and pendants of bone or ostrich eggshell or freshwater shell.

The Jomon Foragers of Coastal Japan

Jomon refers to a cultural complex and time period that was found in the Japanese archipelago from circa 14,000 BCE to circa 300 BCE. The name is derived from the characteristic cord-impressed pottery that was in use at the time; the Japanese term *jomon* means "cord-marked." The Jomon were hunters and gatherers. In fact, part of what makes this archaeological culture unique was its use of pottery without the adoption of domestic animals or agriculture.

The oldest pottery in Japan—in fact some of the oldest pottery in the world—was excavated from the Odai Yamamoto site in Aomori prefecture. Radiocarbon dating of adhesions on the surface of the pottery date it to circa 13,500 BCE. Other early pottery sites include Fukui Cave and Senpukuji Cave on Kyushu. Despite being classed as Jomon pottery, most of the pottery made during the Incipient Jomon period (ca. 14,000–9000 BCE) has little or no cord marking for decoration. Appliqué, punctuate marks, and linear relief are the major forms of

decoration. Most pottery vessels were deep bowls with either a circular or a flat base.

Many Incipient Jomon sites are found in caves. For open settlements, there are only a few with pit houses; the Sojiyama site in Kagoshima Prefecture is an example. The lithic assemblages from Incipient Jomon sites are dominated by spear points and tanged blades, with only a small percentage of grinding stones. This would imply that the subsistence was focused on hunting.

The Initial Jomon period (ca. 9000–5500 BCE) is marked by more open settlements with pit houses, changes in subsistence, and new pottery shapes and styles. The pottery of the Initial Jomon period is characterized by deep bowls with either conical, round, or flat bases. It is in this time period that cord marking is used for decoration.

Natsushima in Kanagawa Prefecture is a large shell-midden site from the Initial Jomon period. A variety of shellfish, fish, and land mammals were found in the midden. The presence of chipped stone adzes and grinding slabs indicates the exploitation of plant foods. No evidence of pit houses was found at the Natsushima shell midden.

Elsewhere in Honshu most Initial Jomon sites are small, containing only a few pit houses. In Hokkaido and Kyushu, though, sites were found with many pit houses. The Nakano B site in Hakodate had more than 500 pit houses. Not all were contemporary, since they overlap; this indicates that the site was repeatedly occupied. In Kyushu, the Uenohara site had more than 40 pit houses. The excavators believe that only 13 or 14 houses were occupied at any one time at Uenohara.

The Early Jomon period dates from circa 5500 to 3600 BCE. Compared to the Initial Jomon period, there is an increase in the number of large settlements and an increase in the number of storage pits.

New vessel forms such as the shallow bowl and storage jars characterize pottery made during the Early Jomon period. New decorative motifs also appeared.

Lacquerware, while produced during the Initial Jomon period, is more common in Early Jomon sites. Lacquer is made from the sap of the lacquer tree (*Rhus verniciflua*). Jomon lacquer ware is characterized by being primarily red

Lacquered vessel, Japanese, early Jomon period, about 5005–4996 BCE. This bowl, which originally had a lid, has well-defined rim-decoration marks made by jabbing with a stick, bone, or fingernail. The main body has cord decoration. (Erich Lessing/Art Resource, NY)

with a minimal use of black. The red color was made by adding either iron oxide or cinnabar to the pottery.

Torihama in Fukui Prefecture is an Early Jomon shell midden north of Kyoto. Situated along a river, the site was waterlogged, and there was excellent preservation of organic materials. Basketry fragments, hunting bows, lacquer ware, and the prow of a boat were just a few of the wooden objects recovered in excavation.

The earliest occupation at Sannai Maruyama in Aomori Prefecture began during the Early Jomon period. The number of pit houses fluctuated throughout this period, but there are substantial midden deposits. Present analyses of the floral and faunal remains point to occupation of the site in the spring through the fall but provide little evidence of the site being occupied in the winter.

A broad range of resources were used for subsistence during the Initial through the Early Jomon periods. Nitrogen and carbon isotope

THE JOMON FORAGERS OF COASTAL JAPAN

Period	Date
Incipient Jomon	14,000–9000 BCE
Initial Jomon	9000–5500 BCE
Early Jomon	5500–3600 BCE
Middle Jomon	3600–2500/2000 BCE
Late Jomon	2500/2000–1200/1000 BCE
Final Jomon	1200/1000–800/300 BCE

The above chart gives the approximate starting and ending date for each period of the Jomon. There is a range of dates for the beginning and ending dates of some phases since the change did not necessarily occur instantly throughout the Japanese archipelago. Before the widespread use of radiocarbon dating in Japanese archaeology, the relative chronology was based on the excavation of stratified sites containing different styles of pottery. For the Jomon, pottery styles were based on the shape of the pottery and its decoration.

—Mark Hall

data from human skeletal remains indicates that most of the foods eaten were plants. In the spring and summer, grasses, roots, and shoots could be collected and eaten. Acorns, chestnuts, and fruits were collected in the fall. Nuts could have been stored or eaten shortly after collecting. The hunting of deer and boar occurred primarily in the winter. Harpoons and fishhooks found in shell middens suggest the exploitation of marine mammals and fish. Study of the bones in several midden sites indicated that a variety of freshwater and marine fish were eaten. Large shell middens, such as Natsushima and Torihama, point to the exploitation of shellfish during the Initial and Early Jomon periods.

Plant cultivation may have begun sometime in the Early Jomon period. Crawford's work on the Kameda Peninsula in Hokkaido found that there was a qualitative increase in grasses, such as barnyard grass (*Echinochloa*), from the Initial Jomon period through the Early Jomon period. Since barnyard grass is a plant that thrives in sunlight and on disturbed soils, Crawford argues that this increase is due to human modification

of the environment. It needs to be kept in mind, though, that while the Initial and Early Jomon people may have cultivated some plants, it was not done at a level that produced a surplus, and it did not produce a staple food.

While all of these resources existed for the Jomon to eat, it does not imply that they stayed year-round at the same site during the Initial and Early Jomon periods. Habu's analysis of the artifact assemblages and the settlement pattern for the Early Jomon period of Kanto indicates that the inhabitants of this area were probably collectors who moved their settlements seasonally.

The Persistence of Hunting and Gathering in Mesolithic Europe

As the last great European ice sheet began to melt circa 10,000 BCE, hunter-gatherers and their prey began to migrate north to colonize new territory. Global warming was occurring relatively rapidly and driving ecological change characterized by shrubs and trees advancing into tundra. The first tree species to migrate onto deglaciated and tundra landscapes were birch and pine followed by the more warmth-demanding oak, elm, and lime. The increase in plant biodiversity offered a broader resource base than the treeless tundra and encouraged the northward spread of animals such as elk, red and roe deer, aurochs, wild horse, and wild pig. Cultural repercussions were also rapid as the Upper Paleolithic traditions disappeared, to be replaced by those of the Mesolithic between 8500 and 3500 BCE. Thus, it is a transitional but distinctive period between the old and new

stone ages. The Mesolithic is particularly well represented in northwestern Europe; in southern Europe and the Levant (eastern Mediterranean) it was either short-lived or nonexistent, as Neolithic innovations such as the onset of agriculture, permanent settlement, and the production of ceramics directly replaced Upper Paleolithic traditions.

One major difference between the hunter-gatherers of the Upper Paleolithic and the Mesolithic is the latter's adaptation to the closed habitats of forests in contrast to open tundra environments. Other differences include a broadening of the resource base, with hunter-gatherers exploiting coastal habitats, lakeside habitats, and forests. Exploitation of forest resources is especially interesting, as there is little evidence for such use in earlier (interglacial) warm stages or indeed for Neolithic plant and animal domestication and permanent agriculture. Why the opening of the current warm stage should be so different is open to question. Possibly the rapidity of climatic/ecological change forced rapid adaptation, or it may have been a case of population pressure combined with environmental change. Mesolithic communities were nomadic, probably operating from seasonal camps. Their subsistence strategy was based on hunting and gathering, although there is more evidence of hunting in bone remains in archaeological sites than of gathering because plant parts readily decompose and preserve well only in waterlogged environments. While large wild animals would have been the major source of protein, smaller mammals such as badger, otter, and beaver were probably hunted for skins and furs. It is likely that dogs, the earliest domesticated animal, were used for herding; that they were held in high esteem is reflected in the fact that their bones are present in many Mesolithic sites. Mesolithic sites near coasts often contain debris from marine organisms such as shellfish (e.g., oysters and mussels), fish, porpoises, dolphins, and seals, which provided a significant source of protein. The inhabitants may have exploited both terrestrial and marine resources. In some cases, as in those of the Erteboelle region of Jutland in Denmark, vast numbers of bones from various bird species attest to large-scale hunting and/or trapping.

Beaver jaw, ochre, stone tools, and assorted bones, as they were found in situ at a Mesolithic cave burial in Arene Candide, Italy. (Gustavo Tomsich/Corbis)

In common with their Upper Paleolithic ancestors, Mesolithic people employed well-defined strategies to obtain food and were not just opportunistic hunter-gatherers. Of particular importance was the use of fire as a means of manipulating the forested environment and animal herds. Fire, for example, opens up dense woodland, promoting new growth with a high water content that is favored by browsing animals. Evidence for this is widespread in moorland, heathland, and forest environments in Scandinavia and the British uplands, especially in the North York Moors, the Pennines, and the Lake District, where layers of charcoal in soils have been dated to the Mesolithic period and short-lived declines in tree pollen are recorded. The control of fire would have required skill, but it conferred the advantage that animal-herd movements could be predicted to some degree. Such activities also required collaboration between individuals and groups, which promoted cultural development. The remains of plant foods included berries, nuts, fruits, fungi, and seeds with much regional variation throughout Europe. In Britain, for example, hazelnuts are common in Mesolithic archaeological sites, while species such as strawberry, raspberry, rowan berry, acorn, and sea beet

have been recorded from Danish sites. From Franchthi cave in Greece, a rich but different assemblage of plant remains includes barley, lentil, oats, pear, bitter vetch, pistachio, and almond.

These findings reflect the varied characteristics and practices of Mesolithic cultures in Europe, which were far from uniform due to varied conditions along a north-south and east-west axis. Five major divisions are recognized: Maglemosian in Scandinavia, the Baltic countries and eastern Britain, the Beuronian of central Europe and western Britain, the Epigravettian in the Mediterranean zone (Italy, Balkans, and Greece), and the Sauveterrian of western France and Iberia. The characteristics of Mesolithic dwelling sites are not well known, probably because they consisted of materials that readily decompose such as wood and turf and because many sites were submerged by rising sea levels of the early postglacial period. Hearths and postholes are the most widespread indication of former structures. One exception is Star Carr in the Vale of Pickering, North Yorkshire, in Britain, where a birch platform was constructed in reed swamp at the edge of a large lake circa 10,500 BCE. It was occupied for some 300 years. Subsequent waterlogging has preserved this famous Mesolithic site, which provides much evidence for hunting and gathering, boats, tool assemblages, stone and amber beads, and antler headdresses, which may reflect ritual practices.

Mesolithic sites are characterized by distinctive stone tools with microliths, relatively small finger-sized tools in contrast to hand-sized Paleolithic tools, as a common denominator. Arrowheads, blades, adzes, picks, and scrapers were sculpted from a variety of stone types, most commonly flint, quartz, quartzite, and obsidian. Moreover, wood, antlers, and animal bones were also used as tools (e.g., antlers from deer or elk were set in wooden shafts and used as mattocks, or pickaxes, possibly for digging up edible roots and tubers). Water craft (similar to dugout canoes) made of wood and skins were also being used during the Mesolithic. The site of Tybrind Vig in Jutland, Denmark, has yielded two canoes with decorated paddles; the largest could carry six to eight people, contained rock as ballast, and has evidence for a small fire in the stern that may indicate eel fishing. Such vessels were also

used for transport at a time when sea levels were rising and Mesolithic groups were actively colonizing islands, as in the Hebridean Islands of Scotland.

The Archaic in the Americas

The Archaic is an archaeological term for the era that covers all of the Middle Holocene and parts of the Early Holocene in North and South America. In North America this stage covers the time between the Late Pleistocene and Early Holocene peoples who used a fluted point technology, such as Clovis and Folsom, and those peoples who adopted some combination of pottery making, burial-mound construction, or horticulture. In South America this stage covers a slightly longer period, usually spanning between the first colonizers of the continent and those people who adopted some form of domestication and sedentism.

First proposed by William A. Ritchie in the early 1930s as an organizing concept for a portion of the Eastern Woodlands cultural region in North America, the stage was soon appropriated and applied to seemingly analogous archaeological complexes throughout North and South America, although the stage manifested differently in each region depending on environmental, climatic, and cultural conditions. For example, in the Plateau region of North America, climatic conditions continued to warm from their Late Pleistocene and Early Holocene levels, becoming more maritime after 8,000 years before the present and allowing conifer forests to move downslope in the north and shrub steppes to replace grasslands in the Columbia Basin. These climatic changes had measurable effects on the peoples of the Plateau, as they shifted their technologies and resource strategies to

THE KOSTER SITE

The Koster site is stratified within a thick suite of Holocene deposits in a minor tributary valley of the lower Illinois River. Located between limestone bluffs and upland loess or till plains to the east and the Illinois floodplain to the west, the site was initially excavated by Gail Houart in 1971. Evidence from the site indicates that occupation began intermittently during the Early Holocene but that by the Middle Holocene, occupation of the site became intensive. Asch and Ford found evidence that human inhabitants were fishing, hunting deer, and intensively gathering wild plants. Occupation during the Middle Holocene was of long enough duration that permanent structures were constructed, and evidence has been recovered indicating that occupants also used roasting pits, grinding stones, limestone, and hematite plummets for bolas to kill ducks and also used fishhooks, stone knives, and atlatl points in their subsistence activities.

Geomorphic evidence from the site, instrumental in constructing an accurate paleoenvironmental

picture of the Illinois River valley, indicates that Archaic occupants may have temporarily accelerated disturbance of the vegetation cover and soil mantle during the course of food and fuel procurement, leading to local resource patchiness and possible demographic restructuring.

LA PALOMA

La Paloma is an Archaic village located just north of the Chilca Valley on the coast of Peru dating between 7,700 and 5,000 years ago. The site covers about 37 acres (15 hectares) and is situated on a series of low hills. Evidence indicates that the prehistoric peoples of La Paloma exploited four different resource zones in addition to the coastal desert: the littoral (or coast), the river valleys, the *lomas* (hills), and the western flanks of the Andes. Out of these zones evidence indicates that the peoples of La Paloma subsisted largely on marine resources, principally fish and mussels or other bivalves. Floral materials and terrestrial vertebrates indicate some use of land-based resources such as deer (*Cervidae*) and guanaco. The peoples of La Paloma also exploited more distant river valleys for reed and other riverine resources. Paleobotanical evidence indicates that human pressure on plant and other resources, coupled with the decreasing availability of local moisture, encouraged the

prehistoric peoples to focus their subsistence economy on littoral and riverine resources over time.

➤ GUILÁ NAQUITZ

The archaeological site of Guilá Naquitz is a small cave located about 3.1 miles (5 kilometers) northwest of the present-day town of Mitla, in the state of Oaxaca, Mexico. Situated at the base of a large cliff, the site was originally excavated by Kent V. Flannery and colleagues in the 1960s. A total of five natural strata covering over 55 inches (140 centimeters) of depth characterize the site, which has been dated to 8,900–6,700 before the present (BP) and has supplied important information on the domestication of maize.

The preceramic cave deposits are divided into five strata (zones B through E plus the topsoil), from which parts of cultivated bottle gourd (*Lagenaria*) were recovered from zone C and upward. From zone D and upward seeds and peduncles of cultivated summer squash (*Cucurbita pepo*) were also recovered. In zone B grains of teosinte and *Tripsacum* were recovered, supplying information on the domestication date of maize. This evidence indicates that a generally cooler yet more xeric climate prevailed during much of the occupation of Guilá Naquitz and that a maize-like plant was being cultivated by the peoples inhabiting the cave by 7000 BP.

ward newly emerging resources. Evidence indicates that reliance on salmon as the predominant resource was minimal for the first part of the Archaic but began to improve in the Fraser River system by around 5,500 years before the present as a result of these overall climatic changes, although there is evidence that Plateau peoples exploited salmon throughout the stage. In addition to salmon, people continued to subsist on deer and other ungulates, rabbits, beaver, waterfowl, muskrats, marmots, freshwater fish, small birds, and camas. Culturally, evidence indicates that lifeways continued from the Early Holocene based on overall tool kit resemblances, although projectile points decreased in overall size. Throughout the Plateau, activity continued to be

oriented toward lowlands, while midaltitude valleys were seasonally used and trade and exchange with other regions increased.

In the Rocky Mountains, where resources and climatic conditions did not support semisedentary lifeways, evidence indicates that Archaic peoples followed a more cyclical lifeway pattern alternating between the high mountain valleys during the warmer months and the lower parks and plains in the colder months. The Helen Lookingbill site, for example, is a stratified high-altitude open site in the Washakie Range of the Absaroka Mountains in northwestern Wyoming. The site, which served as a camp located near both quartzite and chert stone sources, contains evidence of continued use from the Late Pleistocene through the Middle Holocene. Archaic peoples used the camp to hunt mountain sheep, bison, porcupine, and other mammals, and the presence of a wide variety of tools, including drills, utilized and retouched flakes, and scrapers suggest that the site was occupied for relatively long periods of time, most likely during the spring, summer, and fall months.

Unlike much of western North America, where access to subsistence resources played a key role in Archaic peoples' lifeways, it appears that lithic resource locations played a larger role in southeastern North America for Archaic peoples. Evidence indicates that during the Archaic period high-quality stone for tool use played a more significant role in settlement adaptations than other factors and that group mobility incorporated the geological occurrence of preferred stone resource locations for tool use. The importance of high-quality stone for tool use was of such significance in some areas, such as in present-day Florida, that Archaic peoples transported lithic cores and flakes considerable distances from inland sources to coastal harvesting sites.

Not all Archaic lifeways, however, were centered around the procurement of faunal resources in North America. In some areas, such as the Great Basin and the deserts of the Southwest and northern Mexico, Archaic peoples appear to have lived semisedentary lifeway patterns that relied heavily on floral resources. Evidence from the Archaic period in the Lower Pecos River region of southwestern Texas and Coahuila, Mex-

ico, for example, indicates that people practiced a broad-spectrum subsistence economy and that they relied heavily on semidomesticated floral resources, especially lechuguilla (*Agave lechuguilla*), sotol (*Dasylirion texanum*), and prickly pear cactus (*Opuntia* spp.). Intensive use of these low-ranked resources indicates that local populations experienced periods of subsistence stress beginning in the Early Archaic and continuing through the Late Archaic, primarily because of Middle Holocene climatic conditions.

Farther south in Mesoamerica, the Archaic stage is not as well known as subsequent stages, although fundamental cultural adjustments were made to the varying physical environments by local peoples during the stage. Reliance on maize did not occur in most areas until the end of the stage, although by 3,000 years before the present at least 30 percent of the diet appears to have been based on cultivated plants in the Central Highlands of Mexico. Along the coast of Mesoamerica, there is evidence of Archaic peoples following a similar lifeway that was increasingly based on forms of sedentism but who instead relied more on seasonal marine resources than on domesticated cultigens. Many of the same general cultural patterns that occurred in North America also took place in South America during the Archaic, such as the rise of sedentism, the construction of ceremonial structures, and the beginnings of domestication. For example, in the south-central Andes at the site of Asana, evidence indicates that peoples did not settle the area until around 10,000 to 9,800 years before the present, and permanent habitation of the highlands was not achieved until approximately 9,500 years before the present. From 8,700 to around 6,500 years before the present, evidence indicates that three important social processes occurred at the site: population growth, residential stability, and the emergence of architectural structures indicative of social complexity. After 6,500 years before the present it appears that these trends begin a relatively rapid decline, with the abandonment of public structures and the length of occupation of the site shortening. By 5,000–4,400 years before the present, residential mobility in the area appears to have been confined to the high-sierra environment, where

ASANA

Asana is located on the north bank of Río Asana at an elevation of 11,270 feet (3,435 meters) in present-day southern Peru. Located in a basin within the relatively flat valley floor of the Río Asana valley, the site contains six stratigraphic complexes dating from the Late Pleistocene (10,500–9,000 BP) for Complex VI through the end of the Middle Holocene (4,400–3,500 BP) for Complex I. Evidence indicates that Asana was first utilized around 10,000 to 9,800 years BP, 800 years prior to permanent habitation of the rest of the south-central Andean highlands.

Asana was situated in an ideal location, allowing prehistoric Andean peoples multiple options in their subsistence pursuits. According to Aldenderfer, the earliest phases of occupation indicate that Asana was first used as a logistical camp monitored from a lower elevation base camp. These early site uses focused primarily on the hunting of guanaco and taruca. Later, evidence indicates that Asana became a residential base that was occupied for relatively long periods of time on an annual basis. By 5,000 BP the scale of settlement at Asana changed, with less residential mobility taking place along with a greater reliance on seeds. By the end of the Middle Holocene, evidence indicates that the guanaco had been domesticated and that this became the primary resource for people of the area until it was abandoned after 3,600 BP.

—Peter Jones

Bibliography

Aldenderfer, Mark S. *Montane Foragers: Asana and the South-Central Andean Archaic*. Iowa City: University of Iowa Press, 1998.

plants were intensively utilized and a series of ceremonial structures were built.

In central Brazil, on the other hand, evidence based on human skeletons, rock shelter stratigraphy, and chronology of open-air sites indicates that large areas ceased to be occupied by Archaic peoples during much of the Middle Holocene as a result of unfavorable climatic conditions. Evidence indicates that Archaic peoples moved to regions of South America where Middle Holocene environments were more favorable, such as along the coast of Brazil. Areas that

maintained a semistable climate, however, appear to have been continually occupied during the Holocene, such as the rock shelters of Santa Elina, Gruta do Gavião, Toca da Esperança, Lapa Vermelha IV, and Lapa dos Bichos.

Similarly, at the rock shelter site of Sabana de Bogota in the El Abra Valley of Colombia, evidence indicates that climate greatly affected Archaic peoples' lifeway patterns. Between 8500 and 5000 years before the present, Archaic peoples practiced a general hunting and gathering lifeway pattern with shifts in frequency of particular species hunted and changes in frequency of specific artifact types, while pounding and grinding implements may indicate increasing emphasis on plant foods. There is evidence of a gradual increase in the human population of the Sabana de Bogota over the millennia until the severe drought around 5000 years before the present reduced or scattered the population in the area. At this time, in the northern lowlands of Colombia, hunting and gathering populations concentrated on the coast or near marshes and lagoons, as evidenced by shell mound accumula-

tion, and on the Caribbean coast pottery appeared by 5,000 years before the present.

■ Introduction: Population Growth through Time

Population growth can be defined as the increase in the number of people per given area of land. In the absence of migration, it occurs when birthrates exceed mortality rates in a population. Population growth is one component within the broader study of human demography, which itself is underwritten by principles of ecology and evolution. Human paleodemography is the study of past population trends, and data is provided by the excavation of skeletal material and archaeological proxies (site densities or frequencies of radiocarbon dates) as well as, increasingly, via the analysis of genetic data from both currently living and ancient populations. As a species, *Homo sapiens* is today one of the most successful large-bodied mammals on the planet, with a global distribution. The archaeological record of the Pleistocene and Holocene charts the dispersal of various species of *Homo* onto all con-

tinents from its former confinement in Africa. Facilitated by key technological innovations, this remarkable dispersal went hand in hand with, was partly driven by, and led to an increase in the total number of people especially since the beginning of the Holocene, which has brought both milder and much more stable climatic conditions. On every inhabited continent, the end of the last Ice Age with its often erratic oscillations in climatic regimes and the subsequent onset of the Holocene are marked by patterns of accelerated population increase. Furthermore, it is clear from historical records, such as parish records and censuses, that over the last few hundred years the human population has grown at an ever-accelerating pace. Indeed, it is today growing so fast that feeding and accommodating these vast numbers of people has been identified as one of the major challenges for the future.

Traditional models of population growth assume that numbers will increase until a certain plateau is reached, around which time numbers will fluctuate slightly. Such a growth curve is termed logistic, followed by a dynamic equilibrium centered on the carrying capacity (K) of the environment. K is defined through fundamental ecological variables such as the availability of sunlight, plant and animal resources, water, etc. In contrast, recent population increases instead follow an exponential growth curve, and a number of studies on so-called natural fertility populations—that is, small-scale societies exhibiting traditional patterns of birth, death, and migration—support the view that human populations have the potential to grow without reaching an intrinsic ceiling. If these insights are extrapolated back into the past, the question arises as to why human population numbers have not increased to their current level and beyond much earlier. The answer likely rests with periodic local declines in human population numbers and growth trajectories that have kept these numbers in check, on occasion dramatically so such as in the case of epidemics or widespread famine. Individual fertility does not depend on the overall economic potential of a given area but rather on people's ability to extract resources for themselves and on their own reproductive efforts. Carrying capacity itself is a fluctuating property of the environment, especially when climatic variability over time is taken into consideration. Humans do not have the ability to predict future climatic trends accurately, and hence K is regularly exceeded, which, unless emigration occurs, leads to other density-dependent regulating mechanisms (e.g., disease, famine, conflict) taking effect. These will decrease population numbers below K , from where renewed cycles of population growth begin. It is against the backdrop of climatic change that human population growth must be considered. One of the key contributions of technology to population growth over time has been as a buffering mechanism against fluctuations in climate/carrying capacity. The contrast between exponential (unlimited) and logistic (limited) population growth may therefore be more apparent than real: When given the opportunity, human populations will in-

GLOBAL AND LOCAL (INSET) POPULATION GROWTH PATTERNS: 1,000,000 YEARS to PRESENT

(Source: M. Livi-Bacci, M. 2007. *A Concise History of World Population* (Oxford, UK: Blackwell, 2007); J. L. Boone, "Subsistence Strategies and Early Human Population History: An Evolutionary Ecological Perspective," in *World Archaeology* 34(1) (2007): 6-25.

crease near exponentially, but climatic factors as well as technological limitations set boundaries, resulting in growth curves that appear to mimic the logistic pattern.

Demography is vital for placing humans in an ecological and evolutionary framework and for understanding both human biological as well as cultural evolution. Population growth is both an effect of cultural changes (e.g., advances in food acquisition technologies) as well as a cause for further such changes (e.g., migration of populations from high-density into low-density areas, the emergence of permanent housing structures, etc.). The once-held assumption of stable or steadily growing populations in the past has been shown to be misleading. Instead, past demography should be thought of as highly variable and linked to patterns of both climate as well as societal change.

The Causes of Population Growth

The study of the causes of population growth considers both intrinsic and extrinsic factors. Intrinsic factors are those that relate to humans as biological organisms and especially so-called life-history parameters. Life history is the summary term for the course taken by an organism through the various biologically and socially defined stages of life (infancy, onset and end of reproductive activity, etc.). The key life-history parameters for understanding population growth are birth, reproduction, and death as well as migration. In contrast, extrinsic factors are environmental or external to the organism. The overall climatic regime within which an organism finds itself has important implications for population dynamics. Climatic changes and events can influence population growth directly through increasing mortality, but much more commonly the environment provides clues that organisms, including humans, use to make their life-history decisions: when to reproduce, how often to reproduce, and whether

to migrate. Beneficial climatic regimes will stimulate more people to reproduce faster, whereas a worsening climate will result in lower birth rates. It can therefore be said that the environment acts as the ultimate cause of population growth, whereas changes in human life-history—increases in fertility and birth rate, reduction in mortality, and increases in lifespan—have to be understood as the proximate causes.

From a historical or an archaeological perspective it is important to note that the environment for humans includes not only basic climatic factors but also other humans as well as the material culture with which we have surrounded ourselves over the course of the last 2.5 million years. Social learning and its material signature, technology, have been shown to be adapted to deal with medium-term environmental fluctuations (individual or trial-and-error learning deals with short-term fluctuations, and biological adaptation responds to long-term changes), and through the built environment and material culture, humans have become increasingly independent, albeit not fully divorced, from episodic climate change. The intrinsic life history of *Homo sapiens* is unlikely to have changed substantially for the last 150,000 years if not more, and patterns of fertility and mortality differ little between foragers and farmers. It is therefore possible to isolate the increasingly efficient buffering mecha-

ESTIMATED PREHISTORIC HUMAN POPULATION DENSITIES AND NUMBERS

Time	Relative population density (persons/km ²)	Land area (in km ²) occupied by humans	Total estimated human population numbers: World
Today*	approx. 44.952	148,300,000	approx. 6,666,400,000
5000 BCE	0.115	75,000,000	8,625,000
10,000 BCE	0.1	6,000,000	600,000
100,000 BCE	0.03	4,000,000	120,000
1,000,000 BCE	0.025	3,000,000	75,000

nisms provided by material culture as having facilitated the dramatic rise in human populations, in particular since the onset of the climatically more stable Holocene period. Key innovations such as the bow and arrow and the use of domestic plants and animals have stimulated episodes of often dramatic demographic growth and expansion of human groups. Agriculture in particular had far-reaching implications for human population growth. The high mobility required of hunter-gatherers limits the number of young children that can be looked after and transported at any one time. As populations settled down around domesticated resources, however, women were released from these constraints. Sedentary lifestyles by themselves are strongly associated with larger populations, even in prehistoric and recent forager populations (e.g., Erteboelle, Jomon, Northwest Coast First Nation groups). In addition, farmers would be able to provide foodstuffs adequate for earlier weaning of infants much more readily than would hunter-gatherers. Earlier weaning coupled with lower rates of mobility would have steeply increased birth rates in early farming populations. Supplementary refinements in agricultural technology, such as the introduction of iron plows, animal traction, and eventually mechanization, are at the root of further demographic increase, and some have argued that population pressure itself stimulates innovations.

No mention of population growth would be complete without addressing its counterpart, population decline. Few if any historically or archaeologically known populations have grown continuously, and the causes for decline are often linked to those for growth. In fact, growth itself can set the stage for subsequent decline, as it will usually go beyond the sustainability of a given environment and thus stimulate higher rates of mortality and a return to lower fertility. In addition, the climate, even during the Holocene, was rarely stable for extended periods, leading to local or regional reductions in population densities caused by migration or increased mortality and decreased fertility due to resource shortages.

➤ BIRTH SPACING AND POPULATION GROWTH IN THE !KUNG

The !Kung (also known as the San) are a tribe of hunters and gatherers who reside in the African Kalahari Desert. Anthropologists Melvin Konner and Marjorie Shostak observe that despite being sexually active and not practicing contraception, they have low fertility. Instead, their fertility rate is affected by birth spacing, which is practiced in several indigenous populations. !Kung birth spacing is thought to be connected to highly frequent and prolonged nursing, which diminishes the mother's ability to conceive during nursing.

The !Kung take parenting very seriously, and motherhood is a daunting task. The bond between a !Kung mother and her child is very intense, and a child often has unlimited access to its mother. Anthropologists Patricia Draper and Raymond Hames discovered that among the !Kung, the presence of older siblings in a family helps parents raise all children more successfully. For a child, the weaning stage can occur as early as two years and last as long as four years of age, and birth spacing averaging at 48 months in traditional !Kung societies is considered ideal. Although it is not considered an intentional practice among the !Kung, birth spacing is thought to be nutritionally advantageous to both child and mother.

How Many Ancestors? (One Million Years Ago)

At around one million years ago, a robustly built early form of human, *Homo erectus*, had emerged out of a previously much greater diversity of hominid species living in Africa and immediately adjacent areas. Although we now have a reasonably good fossil record from this period, estimating population densities in deep prehistory remains exceedingly challenging. We have no contemporary analogs for either the Pleistocene savanna environments in which these hominids lived or their particular behavioral, economic, and ecological adaptations. Although they most certainly bracket the behavioral range of *Homo erectus*, neither other primates nor recent hunter-gatherers constitute fully adequate models for reconstructing demography one million years ago. A convincing argument has been made that group size correlates positively with the size of the neocortex, an area of the brain strongly related to social interaction and mem-

ory. *Homo erectus* displays a marked increase in brain size as well as a number of other morphological as well as behavioral and cultural novelties that set it apart from other hominid species and that may have been instrumental in its dispersal out of Africa. It is likely therefore that the emergence of *Homo erectus* and in particular its dispersal into previously uninhabited places reflect a significant growth in overall numbers. Total population number has been estimated at 0.5 million to 0.8 million globally, with hominids living population densities of between 0.019 to 0.064 persons per square mile (0.00425 to 0.025 persons per square kilometer).

Despite the evident success of the *Homo erectus* population, it has to be kept in mind that during the Pleistocene climatic regimes were extremely variable and that although accommodating this variation may have been part and parcel of successful hominid adaptation, significant fluctuations in population densities and distributions would have been common. Although new fossil finds made over the past few

MOVEMENT OF DOMESTICATED WHEAT AND RICE

decades have greatly expanded the known range of early hominids, there is also much evidence to suggest that the ebb and flow of these populations across the landscapes of the Old World was directed by general climatic patterns and that these early populations—small and isolated and hence fairly vulnerable—were prone to stochastic (i.e., unpredictable) extinction.

How Many People? (100,000 years ago)

The period around 100,000 years ago was critical for the evolution of our ancestors, *Homo sapiens*. A number of fossils from various localities in Africa are known, charting the trend toward a modern human anatomy and a variety of genetic studies that point to the period between circa 200,000 and 70,000 years ago as critical for the formation of the contemporary global gene pool. In other areas of the world, archaic *Homo* species were established, such as Neanderthals in western Eurasia, *Homo erectus* groups in East Asia, and the small-bodied *Homo floresiensis* on the islands of Southeast Asia. Archaeological estimates put the global population numbers of this period somewhere between 125,000 and 1.2 million, although some areas may have been occupied at significantly lower densities. Most recent estimates, based on ecological considerations and minimum population densities derived from ethnographic studies, suggest a global population of approximately 350,000 individuals. Note,

however, that these as well as other estimates at the upper end of the scale include hominid species other than *Homo sapiens*, while the figure of 125,000 has been suggested exclusively for the ancestral populations of *Homo sapiens* in Africa. In fact, calculations of effective population size (N_e), that subsection of a population successfully participating in reproductive efforts (excluding children and postreproductive individuals), based on observed modern genetic variability propose an N_e of only 10,000 individuals. How can this apparent paradox be resolved?

The relationship between N_e and census size (N_c), which includes all individuals in a population, is complex, and a number of factors—population structure, age structure, and family size—impact on their relationship. In particular, extinction rate has been shown to be important: higher extinction rates result in a much greater total population estimate, N_c , in relation to N_e . If the hominid population of 100,000 BCE is thought of as a so-called metapopulation in which regular local and regional extinctions, followed by the recolonization of these areas from occupied areas, were common, raised extinction rates begin to make sense. Extinction rates of up to 30 percent per generation are known from ethnographic settings, and under such dynamic demographic regimes N_e would rapidly converge on estimates derived from ecological and archaeological calculations. Local extinctions and bottlenecks may have been caused by events such as the catastrophic eruption of Mount Toba at circa 70,000 years ago. Additionally, such elevated extinction rates also have implications for the transmission and accumulation of cultural traditions. The period of around 100,000 BCE was witness to the emergence of complex modernlike behaviors, albeit in a patchwork fashion. Local traditions emerge, especially in Africa, only to disappear again after a few thousand years. Steep reductions in population size influence the social transmission of knowledge and can lead to cultural discontinuities. If such discontinuities result in a lowered ability to extract resources from the environment or to buffer against climatic changes, further decreases in population size follow. Hominid demography at 100,000 BCE was highly variable, and it was only sometime later that those populations began

to stabilize and, eventually, to increase, resulting in the dispersal of now biologically fully modern groups out of Africa and the subsequent replacement of archaic populations in all regions of the world.

How Many People? (10,000 BCE)

The Ice Age, which reached its height at around 20,000 BCE, resulted in considerable reductions of human populations in most areas of the world, a so-called bottleneck. As the planet began to fitfully warm up, populations recovered, and the renewed colonization of many high-latitude regions commenced. At 10,000 BCE, human groups relied on a hunting and gathering subsistence economy adapted to flexibly deal with the often pronounced and frequently recurring climatic oscillations of the Ice Age. Populations are thought to have been low, in some areas quite far below the levels recorded in ethnographically known recent hunter-gatherer groups. While both genetic as well as archaeological data have been used to calculate population numbers at this time, precise estimates remain difficult. Maximum global population numbers at 10,000 BCE were around ten million, but there is likely to have been considerable regional variation, with some areas fairly densely settled and others practically devoid of human activity. At lower latitudes, especially in Southwest Asia, larger nucleated settlements began to develop, some of which would have been occupied for a large part of the year by perhaps 200–300 people at any one time. In these areas, sedentary or semisedentary farmers began to experiment with potential domesticates (e.g., emmer/einkorn wheat, sheep, and goat). In contrast, approximations for middle- to high-latitude hunter-gatherer population densi-

ties range from 0.003 to 0.128 persons per square mile (0.001 to 0.05 persons per square kilometer). Given these estimates, California—today the most densely populated state in the United States with an estimated 36.5 million inhabitants—would have been occupied by between 424 and 21,200 highly mobile hunter-gatherers with population networks stretched over vast areas of effectively unoccupied space. Ireland, today home to some six million people, would have been visited by between 84 and 4,221 foragers at the time. Both areas were marginal for human settlement at 10,000 BCE, so actual population numbers would have been toward the lower end of these estimates.

The period around 10,000 BCE was one of relatively benign climate, and populations were most certainly growing and expanding. However, this was not to last, and both a general climatic turn just after 10,000 BCE (the so-called Younger Dryas) as well as unique events such as volcanic eruptions and comet impacts may have had considerable demographic consequences. Much like in earlier periods, it is not possible to postulate steadily growing or even stable populations during this period. Following the Younger Dryas, global climate began to ameliorate, becoming warmer and wetter as well as more stable. This marks the transition from the Pleistocene—the Ice Age—to the Holocene, the current climatic era. Although people faced the challenge of adapting to these new temperate climatic regimes, populations increased by an estimated order of magnitude, now at 0.03 persons per square mile (0.01 persons per square kilometer). Despite rising population densities, significant demographic changes, including pronounced reductions in population size, remain an important factor shaping the Holocene archaeological record.

How Many People? (5000 BCE)

Around 5000 BCE, many areas of the world had recently or were currently experiencing a major transition: the shift from a subsistence economy based on primarily hunting, gathering, and fishing to one based almost exclusively on plant and animal domesticates. In Southwest Asia, where these developments had begun earliest, larger village agglomerations began to emerge. Built of mud-brick houses, these villages would have been home to around 150 people. The development of irrigation agriculture, the use of animals for traction, and the shift toward dairy economies as well as the increased use of tools made of copper—the period of circa 6000 to 3000 BCE is often referred to as the Chalcolithic or copper age—alongside stone implements facilitates a marked population increase in this area. Human settlements expanded into previously unoccupied areas. In many other parts of the world (i.e., western Europe, East Asia) the shift from foraging to farming correlates with the disappearance of Mesolithic (middle stone age) hunter-gatherer-fisher cultures and the emergence of various so-called Neolithic (new stone age) cultural entities. The domestication of plants and animals and their increasingly intensive use is perhaps best viewed as a coevolutionary process, which led to profound demographic changes both in the Old World as well as the New World. The new farming economy led to a more intensive economy, allowing more people to occupy a given area of land. In addition, by reducing the need to move about frequently, it raised the natural limits to how many dependent offspring any one family unit could support. Coupled with the greater availability of weaning foods in the form of gruel and, in some areas, animal milk, fertility rose sharply. Although this rise in fertility occurred in

tandem with an increase in mortality, a decrease in life expectancy as well as a decrease in overall health, rates of population growth increased markedly. This demographic transition has left traces both in the human genome, the skeletal as well as archaeological records. Global population has been estimated to between 5 million and 20 million people, but again there is likely to have been significant regional variation, especially pronounced at this stage because not everywhere had people switched from foraging to farming. In some areas (e.g., the High Arctic) this was simply not practical and was never achieved successfully, while in others relatively prosperous hunter-gatherer-fisher populations were well established and lived at fairly substantial population densities independently of farmers. Overall, however, Neolithic economies based on a range of domesticates did confer a significant demographic advantage to farmers and, on average, lived at higher population densities. However, early farming technology was still severely limited and could only function successfully within fairly tightly circumscribed conditions, namely fertile and easily tilled soils. As a result, such areas were settled first, and populations fluctuated in accord with both climate and cycles of anthropogenic (through human activity) soil exhaustion. These fluctuations as well as their overall great demographic success are reflected in the archaeological record of these early farming populations.

Society and Culture

Despite their apparent simplicity, society and culture are difficult to define. This is especially true for this era, since we must approach them both through the complexities and limitations of the data obtained from the archaeological record. Stones and bones are almost all that we have to define society and culture for more than two million years of our history, and it is only within the past 10,000 years or so that the archaeological record grows in quantity and quality. We are forced once again to rely upon analogy and inference to discuss the nature of social and cultural life of our distant ancestors.

Despite the problems associated with definition, it is important to at least make the effort to define these terms. Society generally refers to the set of relationships between individuals of some group; note that this definition includes both humans and nonhumans. Wolves, birds, and chimpanzees all have social relationships of some kind, and the term “society” is used to describe the nature of relationships between individuals. Chimps have well-defined dominance hierarchies, and each chimp knows his or her place within it, that is, who is above and who is below. These hierarchies influence many aspects of chimpanzee society: who grooms whom, who has sex with whom, and with whom you may share your food.

In modern America, we reserve the term “father” for our male biological parent. To say that someone is your father is to express both a biological and a social relationship. In some village societies in the Amazon Basin, however, the term “father” describes a relationship not only with a male biological parent but also with his biological brothers, who in the United States would be called “uncles.” The biological relationships in the United States and the Amazon Basin are identical, but they are different because the cultures of these groups are different. In one sense, culture is the ways in which social relationships are defined and expressed.

But the concept of culture goes far beyond social relationships and includes the totality of nongenetic behaviors, values, shared beliefs, material objects, and ways of defining and classifying experience within a group of individuals. “Culture” in this sense is a term that is reserved exclusively for humans, since the definition is based on the capacity for symbolic communication that is one of the hallmark traits of our species, *Homo sapiens sapiens*. Although other animal species are capable of learning new behaviors and emulating behaviors based upon direct

Although other animal species are capable of learning new behaviors and emulating behaviors based upon direct observation of them, it is the human capacity for symbolic communication—the ability to use symbols in a creative manner—that makes us unique.

observation of them, it is the human capacity for symbolic communication—the ability to use symbols in a creative manner—that makes us unique. Not only can we learn, we can create wholly new behaviors.

Relying on this definition of culture for the peoples of this era is problematic, however, because much of what the definition entails cannot be directly observed in the archaeological record. Archaeologists have responded to this dilemma by developing the concept of an “archaeological culture.” This definition includes consideration of variability in artifact shape, form, and numbers as they are distributed across space and within a restricted period of time. Variability in artifact types is a proxy measure, at least in part, of variability between cultures. Thus, in the Neolithic Age of western Europe, for example, two well-known archaeological cultures are the Bell Beaker culture and the LBK (for linear band-keramik) culture. Each has a distinctive style of pottery decoration that allows the archaeologist to identify and distinguish them from each other.

Among the critical questions that can be asked of the past, one of the most important is at what point we can identify the earliest expression of human culture. This is clearly related to the problem faced in our attempt to classify our ancestors from a biological perspective: when do we begin to call a species a member of our own genus, *Homo*? If we based this upon the presumed origins of symboling capacity, it would be either *Homo ergaster* or *Homo habilis* that created the first “human” culture. However, stone tools offer little support for this since they vary relatively little over 700,000 to 1 million years. For some, the appearance of the Acheulian tool tradition and *Homo erectus* is a more likely candidate for some form of early human culture. This is also the approximate time frame for the movement of this species out of Africa.

If culture is defined, albeit imperfectly, by variability in time and space in artifact types, how do we make inferences about the social lives of our ancestors? Analogy with modern hunters and gatherers and village peoples is the primary method employed in this analysis. In many hunting and gathering societies, the placement of huts or structures tells us something about the nature of social relationships. Among the San of the Kalahari Desert, people tend to place their huts closer to kin instead of unrelated people. We can thus measure distances between huts found in the archaeological record and get a sense of whether this rule could be applied to these past peoples. Although we cannot know the specifics of the nature of the social relationship between these people in the past, it does provide some insight into their social dynamics.

Sizes of structures or numbers of structures at sites also allow us to make tentative inferences about social organization when combined with inferences about room or structure function. In some societies, large rooms denote either large numbers of people living within them or possibly someone of higher social status. If blocks of rooms known to have been occupied at the same time are spaced far apart, it may be that different social groups of the same archaeological culture were present.

Sometimes artifacts themselves tell us something about social relationships. In the American Southwest, for example, although the ceram-

ics made by these people can be attributed to a specific archaeological culture, subtle differences in the use of specific stylistic designs suggest that distinct families were responsible for their creation.

Thus, while the kinds of evidence about social relationships are sparse, we can often combine them to make inferences about social status, social differentiation, numbers of people present, and more. The contributions to this theme will explore the degree to which we have been able to reconstruct the social relationships of our most distant ancestors.

—Mark Aldenderfer

■ Introduction: The Origins of the Human Family

Despite their best efforts, scholars will never know much about the origins of the human family and its transformations through time. The data from archaeological research is simply too coarse to create a satisfying picture of what ancient families were like, especially in the very deep past. Scholars are thus left with two primary approaches to developing something of an understanding of them: analogies with our nearest primate relatives and analogies with modern hunters and gatherers, village agriculturalists, and pastoral peoples. Our primate relatives are the best source of information for understanding the possible forms of social organization of our earliest ancestors, such as the australopithecines. Although these ancestors walked upright and were capable of making simple tools, scholars believe that their cognitive capacities and behavioral repertoires were limited and were likely more like those of our ape relatives. But researchers also believe that some of their social formations may have been somewhat more complex than our nearest relatives. Unfortunately, anthropologists can offer only informed speculations about what these social forms may have been like.

But our primate relatives do offer a baseline of sorts that is quite important to understand because we have replaced many things seen in the primate world with a bewildering variety of family types, kinship systems, and ways of reckoning social relationships of all kinds. For example, chimpanzees have social formations based upon

mother-offspring bonding, dominance hierarchies based upon sex and age, limited pair-bonding between males and females, limited sociality between nonrelated individuals, and very limited sharing of food, especially meat. The dominance hierarchy is by far the most important feature of chimpanzee sociality. Adult male chimps in their prime dominate chimpanzee groups; by physical means and display threats, they jealously guard mating opportunities with females in estrus, expel younger males from the social group, and, because of their status, receive more grooming from lower-ranking members.

In contrast, dominance hierarchies based upon physical abilities are rare in most human societies. Indeed, many mobile hunting and gathering peoples have a profoundly egalitarian ethos that requires the sharing of meat across all family members present and creates a social context within which attempts by individuals to become dominant in decision making and the hoarding of resources are met with resistance. Although family structures are highly variable across these societies, there is recognition of biological paternity and a wide range of recognized and named relationships between siblings and parents, such that brothers, sisters, aunts, and uncles are now part of the social framework. Pair-bonding is widely recognized in human societies, and these bondings and their outcomes are characterized by complex rules that govern the choice of marriage partners, degree of social mobility, and sets of rights and obligations that are owed to people

who are defined as part of a larger, more extended family.

These complex forms of sociality are utterly absent from the social formations of our primate relatives, and it appears that the ability to think symbolically is important in this transformation. Symbolic expression via language, and to a lesser extent speech, creates a context wherein ideas like “uncle” (your father’s brother, themselves terms that now require definition within the symboling system) or “first-cousin marriage” (a rule that directs you to marry your uncle’s daughter or son) now become possible. Indeed, the very idea of “marriage” is something that is unknown in primate societies but is virtually a human universal. The evolution of our symbolizing capacity, then, is closely tied to the evolution of new social forms.

It is also important to recognize that there is no single, universal form of the human family. Because of our ability for symbolic expression, one can imagine, and in some cases create, distinctive family structures. Early in human evolution, the development of what seems to be the core features of the human family—pair-bonding, recognition of biological paternity, and a definition of relatedness—may have been stimulated by ecological factors related to the division of labor, for example. Over time, however, historical circumstances and tradition become more important as defining features of the definition of the family and its constituent parts. As societies move from an egalitarian ethos to ones characterized by social ranking, families become more about status, prestige, and social power even though the bonds of relationship and recognition may persist. Some societies allow men to have multiple wives, while others recognize marriage but see it primarily as an economic transaction. Very few societies allow women to have multiple husbands. In some places families live together in a single habitation, whereas in others men and women live apart, with children living with women until a certain age and then moving into the company of men after initiation rites. These are all families.

The contributions in this topic will explore this variability and provide summaries of current thinking on these topics. But keep in mind that since these are primarily analogies, they are

our best ideas about what the past might have been like and not definitive commentary on what it was necessarily like.

Primate Families and Their Relevance to Human Evolution

A survey of modern human societies tells us that families can be comprised of various combinations and associations of any number of people, from mothers, fathers, and their offspring to extended family, stepchildren or adopted children, and same-sex parents. The family experience is a varied but important one, and across many cultures the concept is frequently invoked as a powerful metaphor for security and loyalty. Family has also been pervasive in many narratives of human evolution, from the early idea that the nuclear family is a derived human adaptation characterized by male provisioning of the female and the young to the moniker “The First Family” given to a group of adult and juvenile *Australopithecus afarensis* individuals discovered together at Locality 333 at Hadar, Ethiopia. Unfortunately, in exploring the evolutionary meaning of family, we sometimes struggle to separate the cultural from the biological. Family may be defined by cultural norms that shift within and between cultures as well as over time, and it may also be defined by straightforward biological relationships and, in this sense, is easier to pinpoint: a unit of two parents and their offspring as well as other individuals genetically related through the paternal and maternal lineages. In this sense, we all have a family that can be understood along the same lines.

Some scientists interested in evolution ask why, or if, family is critical to the survival of modern humans as a species. In other words, they ask if living and functioning in family units, however they are defined, confers a reproductive advantage, and if so under what circum-

stances they are advantageous and in what conditions this evolved. This is a relevant consideration because humans display unique behavioral and biological characteristics that often function within the context of a family unit. Relative to other mammals, humans have an extremely long childhood with an equally long period of paternal investment. Humans are born altricial (requiring nourishment) and experience an extended maturation during which the child is dependent on its parents and other caregivers while it develops the linguistic and social awareness necessary to survive and compete in a complex social structure. Human females also have a uniquely long postreproductive life called menopause. Although counterintuitive, the cessation of reproduction may actually increase reproductive fitness. It is suggested that menopause evolved to provide the mother with enough time to raise her young prior to death; motherless children would be less likely to survive into adulthood. Additionally, menopause provides time for a woman to increase her reproductive fitness not through the direct care of her own offspring but her children's offspring, thus ensuring that her genetic legacy survives beyond the first generation.

Evidence for how hominin families were organized is not explicitly fossilized, so in order to extrapolate this information anthropologists frequently use primates as models to test theories of evolution against both the paleoanthropological record and modern human behavior. Primates are good candidates for this approach because not only are they our closest living relatives, but they also have a clear sense of their own families; all primates recognize their kin, and when protection or provisioning is required, preference is given to related individuals. In hierarchical primate societies, family membership even determines one's own status.

While cultural definitions of family are inappropriate to apply to nonhuman primates, we can investigate the biological relatedness of individuals and how this relatedness influences the composition of living groups and behavior toward others. These characteristics are determined by each species' reproductive strategy. Strategies range from harems, in which one male controls reproductive access to a large group of

A comparison of skeletal elements of the chimpanzee and Homo sapiens. Humans, as bipedal animals, show real differences in limb proportions and shapes when compared to the chimpanzee, which is only occasionally bipedal. This example provides good insight into the skeletal traits anthropologists examine when seeking to determine when our ancestors became bipedal. (Illustration by Jeff Dixon)

females but does not invest in their offspring (such as gorillas), to monogamy, in which one male and female mate exclusively. Primates are unique among mammals in that many species—perhaps 10–15 percent—are understood to be monogamous. This poses yet another problem in definition. Not only is monogamy a culturally loaded term, but biologically it can relate to two different things. One is a reproductive strategy in which one male and one female mate but the father provides no direct support for the offspring, and the other also describes a social structure characterized by joint paternal investment, parental pair-bonding, and family living units.

The golden standard for primate monogamy models has not been our closest living primate relative, the chimpanzee (which lives in multi-male, multifemale groups where exclusive mating opportunities do not commonly persist), but gibbons. However, recently it has been shown that gibbon pair-bonds are not lifelong but instead last from several months to several years and that within the general social structure there is a degree of flexibility not previously appreciated. It is likely that lifelong reproductive partnerships are not the evolved biological norm for humans either, with accumulated evidence supporting the conclusion that humans practice polygamous mating strategies and that multimale, multifemale groups have been common throughout much of our recent biological history.

However, it is clear that human adults often practice a mating strategy that involves pair-bonding and investment in the young regardless of modern cultural mores regarding monogamy. How can the evolution of this phenomenon be investigated in the hominin fossil record? We know from studies of primates and other mammals that in species where males must compete for access to the mates, there is a high level of dimorphism, or size difference between the sexes, but in species where there is little competition for mates, such as scenarios characterized by pair-bonding, there are lower levels of dimorphism. Therefore, we can use a decrease in hominin sexual dimorphism as a proxy for the evolution of pair-bonding and paternal investment. The initial evidence for such a decrease is found in *Homo erectus*; this taxon is often perceived as representing the first major step toward a reproductive strategy in which pair-bonding, and thus an inferred monogamous social structure, is critical. Recent evidence suggests that *H. erectus* may be more dimorphic than previously appreciated, so the issue of hominin family organization remains debatable.

Primate Reproduction and the Origins of Families

The study of primate behavior is of great importance to understanding the evolution of human behavior. One of the richest topics to be explored through primatology is the evolution of group living, or families, in humans. There are many possible reasons that group living evolved among humans, but the primary factor was to increase survival of both individual and offspring. With the exception of the orangutan (*Pongo pygmaeus*), all higher primates live in complex social groups. Chimpanzees (*Pan troglodytes*) and bonobos (*Pan paniscus*), our closest genetic relatives, the core of these groups is comprised of related individuals. Changes in group composition as well as behavior within and between groups tend to be ultimately based upon reproduction and attempts to maximize reproductive opportunities. Primate reproductive strategies are highly varied throughout the order. However, certain trends dominant in higher primates are also parallel to those found in human populations. Human pairings are most frequently patriarchal, consisting of a monogamous pair or one man with multiple wives. Gorilla (*Gorilla gorilla*) groups are frequently comprised of one male with various females. Understanding the similarities as well as the differences between humans and nonhuman primates can reveal possible selective pressures involved in hominid evolution.

On a biological level, females are the limiting factor for reproduction. Males can inseminate females at a much quicker rate than females can reproduce. Also, female investment is much higher because once the offspring has been born, nursing leads to more parental investment from the mother than the father. Thus, females must be much more selective in choosing mates because they invest more at a biological level. Therefore, males must develop more competitive strategies in order to gain mating opportunities with females. This is observable in higher aggression rates between males than females in mating

situations. In one-male multi-female groups, such as gorillas, males will often attempt through violent interactions to keep outsider males from mating with their females. Group living for females in these situations is beneficial because they gain protection from outside males. In multimale multifemale groups, as seen in chimpanzees, females will often bond with certain males in order to gain protection for themselves and their offspring. Females in these groups will often display receptivity for mating through estrous, or labial swelling. These swellings remain quite prominent before and after the peak of the estrous cycle. It is theorized that this creates confusion about paternity, thus keeping threats to offspring low among males who may be unsure of whether or not it is theirs. These are biological adaptations that have occurred in the face of certain pressures. In humans, intersexual and intra-sexual interactions may have evolved due to similar pressures. For example, men tend to be larger than women, possibly because of the need for more visible, direct competition for females with other men.

At a behavioral and ecological level, group living has many benefits for primates. It is easier to monopolize resources and defend against predators in groups. Since related individuals share genes, which they are inherently driven to protect for passage into future generations, the chance of gaining support in conflict or gaining access to food are increased when living in family units. Dispersal occurs in situations when the individual can increase mating opportunities by joining other groups. This is observable in chimpanzee females, who will leave their natal group when displaying estrous swellings in order to gain tolerance from new males. Although in humans various traditions involving the female leaving her family to join another (an example is dowry) may seem to be directly related, it is important to note that these are cultural structures that may or may not have origins in biological and behavioral evolution. However, it has been proposed that patriarchal societies are dominant due to the nature of male-male relationships as selected by evolution. In other words, since males must cooperate in order to maximize survival, female dispersal may have been the result of such selective pressures. Presently there is

still disagreement as to whether predation or increased access to food sources is the primary factor in the evolution of group living. However, they are both highly significant to human and nonhuman primates.

The Social Organization of the Australopithecines

Between 4.2 million to 1 million years ago, several hominin species lived in a diverse mosaic of habitats in sub-Saharan Africa. Collectively this group of human ancestors is referred to as the australopithecines. They possessed a suite of derived characteristics including smaller canines and the ability to walk bipedally. The australopithecines can be divided into two sister groups, colloquially referred to as gracile and robust australopithecines. The gracile species include *Australopithecus anamensis* (4.2 million–3.9 million years ago), *A. afarensis* (4 million–2.9 million years ago), *A. africanus* (3.3 million–2.3 million years ago), *A. garhi* (approximately 2.5 million years ago), and possibly *A. bahrelghazali* (3.5 million–3.0 million years ago). The robust australopithecines are characterized by a dentition and facial architecture adapted to a specialized diet of tougher foodstuffs and are generally given their own genus name, *Paranthropus*, on account of this distinction. Robust species include *P. aethiopicus* (approximately 2.5 million years ago), *P. robustus* (1.8 million–1.0 million years ago), and *P. boisei* (2.2 million–1.3 million years ago). A final species, *Kenyanthropus platyops* (3.5 million years ago), is distinguished by a very flat face. It is difficult to interpret how *K. platyops* fits into the hominin family tree, but this species bears some similarities to *P. boisei*.

Nonhuman primates, like humans, are social creatures. Humans evolved from a common ancestor, and it is therefore reasonable to ask if the australopithecines adopted similar social structures to those seen in our closest primate relatives. Plio-Pleistocene hominin habitats were typified by various degrees of woodland habitats

Illustration of a group of African hominids (*Australopithecus afarensis*) living three to four million years ago. (The Natural History Museum, London/The Image Works)

where there was certainly a risk of predation. Group living may have been a selective adaptation against this threat, and the fossil record provides some clues as to the nature of the organization of these social groups. Sexual dimorphism (i.e., sex differences exhibited between males and females of a species) can be used as an indicator of social organization. In particular, body size differences between males and females are greater in primate species, where there are high levels of competition among males for access to mates, and this has implications for other aspects of social behavior. Assessments of male and female *A. afarensis* and *A. africanus* body size indicate that both species showed levels of body size dimorphism that are larger than those seen in our closest living relatives, chimpanzees and bonobos. This implies that these two australopithecine species lived in a social structure where high levels of male-male competition prevailed. Sex identifications in the fossil record of both species indicate that there is less of a bias against males, as one might expect if the australopithecines lived in harems like gorillas. This provides evidence that male-male aggression occurred in the context of a social structure more similar to chimpanzees in which several males of the same group compete for reproductive access to females. In contrast, recent studies of sexual dimorphism and patterns of growth in *P. robustus* males tell us

that this species of robust australopithecine exhibited levels of sexual dimorphism as high as those seen in gorillas and may have adopted a haremlike social organization where one male monopolizes mating access to a number of unrelated females. In this context, maturing males form bachelor bands or travel as solitary males until each individual is large enough to take over another male's harem. A sex ratio of nearly 4:1 male to female *P. robustus* specimens found in the fossil record indicates that this scenario is likely due to increased predation of these solitary males. Other evidence for australopithecine group living comes from male and female body size ranges, which are similar to those observed in bonobos (*Pan paniscus*), who live in groups of around 30 individuals. However, as bipedal mammals, australopithecines may have been able to increase their home range size to encompass larger areas where resources could be exploited to support much larger groups.

Alternative forms of evidence confound our investigations. In contrast to chimpanzees, bonobos, and gorillas, the australopithecines all have relatively small canines. Large canines in primates are used as weapons and in threat displays, and canine size dimorphism occurs in species whose males exhibit a high frequency or intensity of aggression. Canine size in the hominin lineage gradually decreased during the early stages of evolution, as did levels of canine size dimorphism, although body size differences remained high. From this we can infer that social organization in australopithecines may not be analogous to that observed in primates living today. Problematically, in order to assess levels of sexual dimorphism, anthropologists rely on their ability to identify the different sexes in fossil taxa, but given the fragmentary nature of the fossil record, sex determination can be difficult. Additionally, identifying hominin fossils to the correct species is tricky; some researchers claim that size differences observed in species such as *A. afarensis* may not relate to sexual dimorphism but could be the result of two species of different body sizes being grouped into one taxon. Further discoveries of hominin remains retaining sex and species-specific characteristics will help to clarify the picture.

Early Human Social Organization—*Homo ergaster* and *H. erectus*

Around 1.8 million years ago, at the very beginning of the Pleistocene epoch, hominin evolution makes a major shift. By this point, natural selection has shaped the hominin body to be as efficient as it has ever been and will ever become. This includes growing longer legs and an overall taller stature, which increases stride length for traversing greater distances. In fact, *H. erectus* and the similar species *H. ergaster* are the first hominins to disperse out of Africa, and when they do they roam into various remote tropical and temperate regions of the Old World. On top of that, the brain, which is the main player in social behavior, is large in these creatures, and it becomes even larger throughout the 1.5 million years of their evolution. Furthermore, these species show a major dietary shift toward a greater reliance on animal meat and marrow. With a large brain, a large body, a need to obtain animal resources, and an expanded range, it was only natural that social organization in *H. ergaster* and *H. erectus* evolved as well.

Although we cannot observe *H. ergaster* and *H. erectus* behavior, the fossils that they left behind offer many clues. There are well-known relationships between anatomy and behavior in living organisms. Sexual dimorphism—the difference in body size between males and females—is an indicator of a species' reproductive behavior. Males are generally larger than females in polygynous species, where males must compete vigorously to control a group of mating females. On the other hand, males and females

tend to be of similar size in pair-bonding species, where male competition is not as fierce.

The prevailing hypothesis has been that *H. erectus* showed humanlike levels of sexual dimorphism. If this is true, then we might look to monomorphic ape species such as gibbons and siamangs as a model for *H. erectus*'s behavior. Gibbons and siamangs are pair-bonding species in which males help in caring for offspring. However, recent fossil evidence places the monomorphic image of *H. ergaster* and *H. erectus* in doubt. At Dmanisi, Georgia, and Ileret, Kenya, extremely small hominin individuals have been discovered that appear to be members of the *H. ergaster* and *H. erectus* species. If indeed they are, this could mean that *H. ergaster* and *H. erectus* were much more sexually dimorphic than previously thought. If indeed *H. ergaster* and *H. erectus* were highly dimorphic, then similarly dimorphic orangutans and gorillas offer a better model. In these polygynous groups, males compete for exclusive access to multiple female partners at a time, and as a consequence they are far less involved in the lives of their offspring.

Regardless of the outcome of the current debate about sexual dimorphism and hence reproductive strategies in *H. ergaster* and *H. erectus*, females probably did most of the parenting and foraged for both animal and plant food, while males performed fewer parenting activities and foraged farther afield for relatively more animal resources.

As brains evolved to be bigger, however, infants became increasingly vulnerable. The additional brain growth that humans experience occurs after the infant is born, so the more brain growth that had to be accomplished as brains evolved to be bigger, the more immature neonates became as well. With these increased demands on the mother, male input had to increase, but it is still unclear if this was happening as early as *H. ergaster* and *H. erectus*.

Fossil evidence also offers clues about *H. ergaster* and *H. erectus* foraging strategies that affect sociality. When the preserved bones of hominin prey show stone tool marks overtop carnivore tooth marks, it is an indication that the hominins were not the first to have access to the carcass and probably scavenged for their meal. However, if the cut marks are overlain by tooth

marks, this indicates that the hominins scavenged or killed the prey themselves, and then scavengers worked on the leftovers. Furthermore, if the choice parts of the carcass are the ones marked with stone tools, then that also indicates that the hominins had first access. Without fangs, claws, or a carnivorous ancestry, *H. ergaster* and *H. erectus* had to perfect tool use and cooperation in order to outwit competing scavengers and hunters as they became successful predators.

Although cooperation with group members increased as hunting increased, group size may have dissipated compared to vegetarian relatives, like the great apes, since the closer a species gets to the top of the food chain, the smaller its population density can be. Since *H. ergaster* and *H. erectus* ate more meat than any preceding hominins, carnivore models, like cooperative hyenas and hunting dogs, are often evoked for their social and foraging behaviors and for their patterns of land use.

Although there are a couple of archaeological sites in East and South Africa with purported evidence for campfires (like at Chesowanja, Kenya), the best earliest evidence for controlled fire is from Gesher Benot Ya'aqov, Israel, dated to about 780,000 years ago. Thus, according to the current evidence, it is not accurate to envision *H. ergaster* or *H. erectus*, during the first one million years of their evolution, sitting around a hearth, cooking food, and enjoying one another's company. It is possible that these hominins looked like and behaved like bipedal predatory apes or stone-tool-wielding African hunting dogs more than they resembled humans for a vast stretch of their evolution.

What Do We Know of Neanderthal Social Life?

Neanderthals are a group of humans who have been found in a number of localities in Europe and the Middle East. The farthest east they appeared was once thought to be Teshik Tash in Uzbekistan, but recent genetic research suggests that they also lived at Okladnikov Cave in Siberia. In Europe, Neanderthal sites range in age from around 200,000 to around 26,000 years ago.

Neanderthals represent the descendants of the indigenous or earliest humans in Europe. One can trace their ancestry back to some of the earliest people in Europe and see the gradual development of the short stocky body, protruding face, and other features characteristic of these people. On the other hand, there is little evidence of local evolution of Neanderthals in the Middle East; most likely, they arrived from Europe during a particularly cold stage of the last glacial. While their unique anatomical features had developed as adaptations to cold, dry glacial conditions in Europe, it appears that physiology can only get one so far when the climate changes for the worse.

Neanderthals are the ultimate other, the closest group to which we, as modern humans, compare ourselves directly. Some researchers see them as just a different kind of human; others see them as a separate species. They are seen as being just as capable of surviving as we are and, on the other hand, as being doomed to extinction. Each year brings growing amounts of data about them: new fossils and archaeological sites (belonging to the Middle Paleolithic) as well as ancient DNA samples. Both mitochondrial and nuclear DNA sequences are available for a number of Neanderthals. They show little individual variation in the bits of DNA that reflect history despite their presence over such a large geographic area. But this DNA also supports the idea that they had a last common ancestor with modern humans (meaning "us") no more recently than around 500,000 years ago.

While archaeologists and paleoanthropologists can tell us a lot about Neanderthal technol-

ogy, adaptation, and diet, what can they say about their social organization or social life? If one draws an analogy with modern hunter-gatherers, we would argue that they lived in small-band societies made up of several related families. About 25 to 50 people made up the group. They would be highly mobile, as they were living in glacial Europe. If the genetic data is right in proposing their within-group homogeneity, they would have had to have maintained social interaction over large territories. Possibly, like many hunter-gatherer groups, they practiced a fission-fusion kind of social organization, getting together seasonally for ceremonies and exchanging goods and marriage partners.

What is clear from stable isotope analysis and archaeology is that European Neanderthals were top predators, eating a lot of meat and possibly little else. They lived in cold, glacial Europe and were sort of supernorthern people. From age estimates of skeletons, it appears that they lived a lot longer than earlier humans but had a hard life. Many Neanderthal skeletons show evidence of extreme trauma. But on the other hand, they may have invented intentional burials and so had some notion of the afterlife. In both respects, they become more human, more like us.

Archaeologists would probably conclude that Neanderthals had control over language. They certainly communicated how to make complicated tools, using methods like the Levallois technique. Like archaic humans in Africa, the Neanderthals made composite tools, hafting stone points onto shafts of organic material (wood, bone, etc.). Geneticists have recently demonstrated that the Neanderthals have the same FOXP2 genetic sequence as modern humans have. Certain mutations in FOXP2 today are associated with specific language impairment, an inherited disease. The evolution of FOXP2 shows that it took on a new role in recent humans and is related to speech in some as yet unknown way. If Neanderthals went through the same evolutionary history as modern humans, it was not lack of communication skills that led to their extinction. This is supported by the fact that at least one of them, the Kebara Neanderthal from Israel, had the same kind of hyoid bone in the throat as modern humans have.

➤ DID NEANDERTHALS AND *HOMO SAPIENS* INTERBREED?

Although Neanderthals and modern humans—*Homo sapiens*—co-existed first in the Middle East and later in Europe for many thousands of years, scientists had discovered no unambiguous evidence that the two related species interbred. For much of the twentieth century, most archeologists and paleoanthropologists believed that modern humans replaced Neanderthals either by violence or by being better able to adapt to changing environments. Although skeletal evidence from a few Neanderthals recovered from sites in the Middle East suggested a blending of modern human and Neanderthal traits, this was not seen as conclusive data for interbreeding by most scholars.

The decoding of the Neanderthal genome through the sophisticated analysis of the DNA obtained from three bones from the Vindija site in modern Croatia, dated between 38,000 and 44,000 years ago, has provided direct evidence for the likelihood that at least some Neanderthals interbred with modern humans. The analysis suggests Neanderthals and modern non-African peoples share between 1 and 4% of their genes. Although this is not evidence for widespread interbreeding, the amount of sharing between the two species surprised the researchers.

These new findings present a challenge to a narrow “out of Africa” hypothesis that postulates that all modern humans can trace their ancestry to a small group of people from Africa that replaced all other populations during their expansion from Africa. Although the basic outlines of the out-of-Africa hypothesis remain valid in that the vast majority of modern genetic variability can be traced to these populations, the findings from Vindija suggest that population interactions in deep antiquity were far more complex than has been previously believed.

Bibliography

Green, R., et al. “A Draft Sequence of the Neanderthal Genome.” *Science* 328 (2010): 710-722.

What does this mean in terms of social organization and social interaction? Neanderthals are often seen as less organized than modern humans; they appear to lack the complex artifacts such as jewelry, art, and figurines that are so

► COMPASSION AMONG THE NEANDERTHALS—THE BURIALS AT SHANIDAR CAVE

The Neanderthal burials at Shanidar Cave in the Zagros Mountains of northeastern Iraq became famous after 1957–1961 when the first of them was excavated and popularized by Ralph Solecki. The archaeologist described the burial as being “touched by spirits.” The burial was likely of a disabled shaman who was maintained by his community. It was so impressive that it became the subject of Jean Auel’s popular novel *Clan of the Cave Bear*. Since then, nine Neanderthal burials have been recovered from the cave dating between 32,000 and 49,000 years ago. Burials 1 and 4 offer important insights into Neanderthal lifeways.

Shanidar 1, or Nandy, is the burial of an individual 45–50 years old, which was very elderly indeed for Neanderthals. His life was complicated not only apparently by old age but also by several serious injuries that made it impossible for him to take part in procurement and household activities of his group. His right arm was atrophied and nearly useless (withered and shortened) and had been fractured in several places and healed. He also had a broken and unevenly healed leg, and this injury caused deformation of the lower part of his leg and foot that was probably accompanied with some paralysis down his right side. It made walking a painful process and running impossible. He also had a serious injury to the left side of his face, and it is likely due to this that he was totally or partially blind in his left eye.

In spite of this severe and painful condition, Nandy was maintained by his community and

probably was regarded as marked by spirits since he had managed to survive through so many accidents in his life. Ralph Solecki viewed him as a shaman and assumed that he was a very important person for the community.

Shanidar 4, or the flower burial, represents one of the most striking examples known of a Neanderthal funeral rite. It is the burial of an adult male of 35–40 years old lying on his left side in a partially foetal position. Pollen data taken from the soil that covered the burial indicates the presence there of yarrow, cornflower, bachelor’s button, St. Barnaby’s thistle, ragwort or groundsel, grape hyacinth, joint pine or woody horsetail, and hollyhock, all of which are absent in samples taken in other parts of the cave. This finding implies that these flowers, most of which are widely explored in medical practice as diuretics, stimulants, astringents, and anti-inflammatories, were specially brought to the burial place, probably in connection with the shamanic medical practices of the buried person. It should be noted, however, that some researches tend to interpret the presence of the flowers as the result of natural agencies, such as wind or water transport of the pollens.

abundant in Early Upper Paleolithic modern human sites. All of these are involved in information exchange, the transmission of knowledge from person to person. (But do not forget that Middle Paleolithic Africans did not have much of this either.)

So when it comes down to the facts, what was their relation to us? Were they a separate species, *Homo neanderthalensis*? Or were they just a polar version of us, at most a separate subspecies, *Homo sapiens neanderthalensis*? It is most likely that Neanderthals and modern humans were cousins rather than members of the

same species. But there is growing evidence of their social interaction with modern humans in Europe at sites belonging to the end of the Middle Paleolithic. Referred to as Chatelperronian in France and Spain, they are seen as transitional to the Early Upper Paleolithic of the first modern *Homo sapiens*. Chatelperronian sites, made by Neanderthals, contain the first evidence of bone and ivory tools and jewelry. If Neanderthals were not mating with early moderns, they were certainly interacting with them culturally. Were they becoming acculturated to the new Aurignacian world? If so, it only worked

for a few thousand years. By the time the ice came back at the height of the last glacial maximum, Neanderthals had disappeared, and only modern people were left.

■ Introduction: The Social Organization of Modern Mobile Humans

Although there is considerable variability in the social formations of mobile hunters and gatherers, there are also significant regularities in these societies such that ethnographic analogies can be a useful way to hypothesize what social groups may have existed in the past.

The hunting and gathering lifeway is predicated upon the availability, abundance, and predictability of the wild natural resources that form the basis of the diet. Thus, many hunting and gathering groups who live in more marginal environments where resources or water are limited may move frequently over the course of a year. Groups living in more abundant environments may move less frequently. Thus, the reality of mobility strongly conditions, but does not determine, the nature of social formations within hunting and gathering peoples.

Although individual families are the smallest social formation, groups of families are loosely joined through kinship (either by descent or marriage) to define a band of hunting and gathering peoples. Group size varies considerably and is based upon the adequacy of resources present at any location, but in general, bands range in size from 30 to 50 individuals. Group structure is highly fluid, and individuals, both male and female, may leave one band and move to the location of another where they have kin. Although maximum band size is usually constrained by resource abundance, it is important to recognize that social factors, such as interpersonal tensions, desire to participate in a network of sharing, conflicts over access to certain resources, disputes over sexual infidelity, and other such problems, may well affect the number of people present at any location.

Depending on the seasonal availability of resources, bands may aggregate in favored places, and it is in these seasonal aggregations that marriage partners are sought, trade and exchange are practiced, and important multiband ceremonies are conducted. In one sense, this seasonal aggregation defines the maximal size of the bands that consider themselves to be part of the same social group, which for many mobile foragers ranges in size from 400 to 500 individuals.

Family organization in mobile hunting and gathering societies tends to follow two structural principles: bilateral and patrilineal reckoning of descent. The former recognizes kinship relationships through both the mother's and father's lines. This is a highly flexible form of kinship and one that responds more effectively to movement of individuals between different bands. This is especially important in regions of the world where mobility is relatively frequent due to resource shortages. In contrast, patrilineal descent is reckoned only through the father's line.

Although coresidence of the members of a family within a band is the norm, given that residences are moved often, there is considerable flexibility in the range and social relationships of people present at any location. In some hunting and gathering societies the entire coresidential group moves together, literally picking up the residence and moving it to a new location. Men and women may hunt and forage around this camp, returning to it at dark to share the day's finds. In other groups, however, a base camp, a more permanent residence, may be established. Group composition at the base camp may be more fluid. For instance, males may leave the base camp to go on extended hunting expeditions, and women, children, and the elderly may stay behind. Males

return to the camp after success, and the entire camp may move again to a new location. Women, especially those with younger children, tend not to go on these extended forays to obtain resources and instead stay relatively near the base camp collecting resources. Children and the elderly may help with this. Childcare is generally undertaken by women or older siblings.

In these societies, the division of labor between men and women is clearly tied to mobility. In general, men hunt larger game, whereas women are responsible for gathering plant foods and obtaining small game when encountered. In practice men may gather as well, and there are some instances in which women may participate in hunting larger animals. Women are also responsible for preparing gathered foods and sharing them with the family members present. In contrast, men are responsible for sharing meat with all of the people present at a camp if they are successful in killing a large animal. The failure to share is seen as a major breach of social ethics.

Most mobile hunting and gathering societies are characterized by an egalitarian social ethos. That is, there are no permanent positions of leadership within them, and consequently all leadership is situational and transitory. Thus, a great hunter may have real influence over decisions regarding where and when to hunt but may have limited influence in, for example, a dispute over a marriage or a case of spousal abuse. A healer may have high status because of her ability to cure the sick or interact with the spirit world, but this status does not translate into a more permanent leadership position. Decisions are made by consensus and through discussion, and while some individuals may have more influence than others, there is no obligation on the part of any individual to adhere to the decision of the group.

Hoarding and aggrandizing behaviors are seen as unacceptable activities. Although private property is understood in most of these groups, the concept extends only to personal possessions. Although hoarding of food is difficult to achieve under conditions of mobility, any attempt to hoard is met with ridicule and social leveling by other members of the group. As in any society, there are aggressive individuals who are demanding and sometimes violent. If ridi-

cule fails to prevent such antisocial behavior, people may leave the band and live with other groups to avoid conflict. But under extreme provocation, such aggressive individuals may be murdered through collective action of the band. This kind of homicide is not uncommon in hunting and gathering societies.

Mobility characterized the evolution of our species, and therefore it is likely that many of the social arrangements seen in modern foraging peoples were common in the past as well. These peoples serve as powerful sources of analogy for the interpretation of the archaeological record.

Variation in Social Organization, 50,000–5000 BCE

The period from 50,000 to 5000 BCE sees a vast change in human adaptation and social organization. At the beginning of this period, everyone made their living by foraging: hunting or gathering available foods. Only certain continents were occupied: Africa, Asia, Europe. The first people may have entered Australia around 60,000 years ago but will not enter the Americas until significantly later. (The exact date for the first occupation of the Americas remains subject to dispute. What we know is that people were here at least by the end of the last glacial period.)

There was also more than one kind of human around: Neanderthals in Europe and the Middle East, anatomically modern *Homo sapiens* in Africa and parts of the Middle East, archaic *Homo sapiens* (also known as *Homo heidelbergensis*) in East and Southeast Asia. Soon afterward, according to genetic, fossil, and archaeological data, modern humans begin to

disperse worldwide from an East African center and probably replaced all earlier kinds of people. At the other end of the time scale, things look quite different. By 5000 BCE, the domestication of plants and animals was well established in different parts of the world. People are now relying on the production of various kinds of foods. There are many ways of becoming tied in with domesticates. Pastoralists rely on domestic animals and tend to be quite mobile, moving seasonally from pasture to pasture. Farmers, on the other hand, become tied to their land and settle year-round in the same place. In some places such as the Middle East, the first literate societies have developed by this time, leaving us a written record of their history and concerns.

Clearly a fundamental change has happened by 5000 BCE. It must have involved a social transformation as well as an economic one. But how does one measure the varieties of social organization in the past without access to written records? Anthropologists define social organization as the way people reckon relationships between individuals within a society. Who is a member of the same family, the same clan, and/or the same village? Members of most societies worldwide as well as anthropologists distinguish between affines, relatives by marriage, and consanguines, relatives by blood. But who falls into these categories depends on social norms and practices rather than just biology.

By 50,000 years ago, modern humans have been present in Africa for at least 150,000 years; Neanderthals have been living in Europe for the same length of time. Early modern humans, or *Homo sapiens*, disperse out of Africa by 50,000 years ago and colonize Europe, Asia, and Australia soon afterward. In Europe and Asia, they come into contact with other kinds of people; our genetic record suggests that there was no significant interbreeding between natives and newcomers.

What kind of social organization would they have had? We are not sure what group size would have been. By analogy with historic and modern foragers, members of band societies, there may be 25 to 50 people in a single group. Perhaps they practiced seasonal fission-fusion; larger groups could get together when resources were most available. At these times of years, they could

have exchanged information and marriage partners. If territories were established, marrying into another group might give one access to their land and resources; this would be a critical advantage in times of stress.

Early modern hunter-gatherers would have probably exhibited a division of labor by age and sex. People would own their own personal property but little else. We imagine hunter-gatherers as mobile, but there are examples of ones who are more or less sedentary. (Usually this is in regions with rich natural resources, such as on the coastlines.) If they were highly mobile, they would have significant spacing between individual births. Mobile women can nurse only one child at a time and thus might have had a child every three years.

How did they make a living? A useful way to look at this is Lewis Binford's idea of the range of hunter-gatherer lifeways from foragers (people who move seasonally from place to place) to collectors (people who settle more or less permanently and who move resources to people).

Contrast this with the situation around 5000 BCE. Now there are farmers with domesticated animals and/or plants in large parts of the Old World. The plants and animals they use vary from place to place, but the basic social pattern could be similar. Early farmers were possibly still living in small groups, but they most likely were sedentary, living in the same place year-round and tending to fields and animals. If one relied on domestic herd animals, like modern pastoralists, they could have been more mobile. But this is not always the case. In the Fertile Crescent of the Middle East, people were settled permanently as hunter-gatherers by 18,000 years ago and seem to be experimenting with wild cereals (the Natufians). Yet during the Archaic period in the Tehuacan Valley of highland Mesoamerica, people were mobile for thousands of years after plants were domesticated, so there is more than one way to become a successful farmer.

Anthropologists have argued that increased sedentism led to reduced birth spacing between children and therefore to increased population. Children also were useful; they played an increasing role in looking after animals or fields. If population increased, there would have to be

changes in the economy to support them, and social networks might have grown larger and larger. By 5000 BCE in the Middle East the first cities have developed, ushering in a way of life that most of us participate in today. Without agriculture, this would never have happened.

■ Introduction: Social Life and the Family in Early Village Communities, 15,000–5000 BCE

For more than one million years, roughly until 15,000 BCE, humans lived a mobile existence. Families moved in concert with the seasonal variability and lived in temporary bases occupied for varying duration. Some groups, especially those living in arid environments, moved relatively frequently, while those in more abundant places moved less frequently. Individual families were responsible for their own subsistence needs, but sharing of meat was common between families. Except in harsh, very cold environments, storage of food was uncommon, and when food was stored it was for family consumption in the winter months and was not used for other purposes. Family structure was fluid, and individuals could and did move to places in which they had kin.

Sedentary life utterly transformed human society. Being sedentary means living at a single location for most, if not all, of the entire year. More permanent places on the landscape of this kind are called villages. Villages are composed of a cluster of residences and their associated structures, and they vary considerably in size. However, most early villages in the prehistoric world probably had no more than 500 permanent residents, and most were far smaller. Over time, and especially in very favorable environments, as societies became more dependent upon agricultural production and more capable at it, some villages grew to be very large and had many thousands of residents.

Village life is generally based upon some form of subsistence agriculture, although there

are a number of early villages, especially in the ancient Near East, that had subsistence systems focused upon extraordinarily dense stands of wild plants, like the ancestors of domesticated wheat and barley or other plant foods. Because villages are permanent, the people who live in them must store food for the winter months or the dry season when agricultural activities are not possible. Furthermore, they must store some of the seeds as well for the next year's crop. In most societies dependent upon agriculture, most adults and older children are involved in subsistence-related tasks at different times of the year.

Villages are composed of households, which are the primary economic unit of the village. In most villages, the household is economically self-sufficient, growing its own food, making its own clothing and tools, and, when possible, generating sufficient surplus for trade or exchange with other households for items that they are unable or unwilling to produce. Households generally have a division of labor based primarily upon gender. Women performed domestic tasks, and men performed tasks outside of the household. Household members cooperated in major agricultural tasks like planting, weeding, harvesting, and preparing grain for storage. However, there are instances where there is communal sharing of resources. Some of the earliest villages in the Near East, for example, had communal storage areas, indicating that while households obtained the resources, they were shared among all village members.

The family is the core of the household. Ethnography shows that family structure within villages is highly variable. Both nuclear families, composed of a married couple and their children, and extended families, composed of a nuclear family, their parents, or other relations, may be found in small and large villages. Families are organized into lineages, which are groups of related individuals who can trace common descent according to some principle. Common forms of descent include patrilineal, where individuals trace relationships through their father; matrilineal descent, in which it is reckoned through the mother's line; and bilateral kinship, where it is traced through both. In many villages, marriage partners are to be found from other lineages. The smallest villages are usually composed of a single lineage, but as they grow larger they contain multiple descent groups.

Politics in a village can be complicated. Within the lineage, leadership is exercised by elder adults, either male or female, depending on the descent principle. Large lineages with many families are often dominant within a village, but they must act by consensus with the other lineages present.

Variation in Early Village Communities in the Near East

There is very significant variability over time and across space in the social and political organization of villages in the ancient Near East. In part, this is related to changing subsistence strategies over time. At 20,000 BCE, all peoples living in the region were hunters and gatherers; at 6000 BCE, almost all people lived in villages and towns and were dependent upon agriculture for their subsistence. Some cultures in the region were based on pastoral nomadism and thus did not live in permanent villages.

➤ AIN GHAZAL, A SMALL VILLAGE IN JORDAN

Ain Ghazal, a small village northeast of present-day Amman, Jordan, was inhabited between 7300 and 5000 BCE. Approximately 30 acres in size, the location was significantly larger than many villages in the Neolithic period of the region. Over 3,000 people lived there, and their lifestyle was similar to other places of early agricultural settlements on the eastern banks of the Jordan River. Archaeologists found houses, graves, tools, bones, and roasted grains. In some areas, remnants of sacred or ritual buildings were discovered. One small circular structure had a white floor and a large fireplace, possibly an altar. In another part of the settlement, a two-room building was cut off by a separation wall and furnished with an altar and a fireplace. Around 6500 BCE the population suddenly decreased, most likely due to drastic changes in the environment.

Among the most important findings from Ain Ghazal are 30 anthropomorphic sculptures also from the early seventh century BC. Considered among the oldest of monumental statues, they included smaller busts and life-sized statues. The sculptures were found in two deposits or pits less than 9.8 feet (3 meters) below the ground surface. One set included statues with detailed bodies but rather plain faces, while the other set has characteristic features of the faces but bulky bodies.

The Neolithic artists built individual parts of their sculptures around a reed skeleton and assembled them. Then they used a bright, almost white, mixture of limestone and clay to shape the statues and marked the eyes with black bitumen and cowrie shells. The reed skeleton extended through the soles of the statue, indicating that they could be attached to a pedestal. Some statues show special attention given to the decoration of their faces. Elaborately polished faces, large and wide eyes, a fine nose, and a small mouth without accentuation of the lips add to the uniqueness of this facial type.

➤ JERICHO—THE WORLD'S FIRST LARGE VILLAGE

The ancient city of Jericho, located in the West Bank of the Palestinian Authority, is 853 feet (260 meters) below sea level and close to the Jordan River where its valley broadens between the Moab and Judean mountains. Jericho is considered to be the oldest continuously occupied settlement and was originally the site of a temporary Natufian camp (a hunting-gathering society) close to the Ain es-Sultan spring circa 11,000 years ago. The camp, with access to a reliable water supply and fertile land, developed into a permanent settlement comprising several low mounds (tells) as agriculture was initiated during the early Neolithic period and expanded to a comparatively large area of circa 9.8 acres (4 hectares). The city was protected by a ditch and robust stone wall 9.8 feet (3 meters) thick with a tall stone tower. It contained mud-brick huts shaped like beehives. Excavations have revealed that domesticated crops were being grown (e.g., emmer wheat, barley, and legumes), while the remains of wild animals, such as gazelle, wild cattle, and boar, reflect the importance of hunting. By circa 9,000 years ago rectangular houses were being constructed, the range of crops had increased, and domesticated animals (e.g., sheep and goats) were being consumed. The burial of human remains in the walls was a common practice.

—A. M. Mannion

Archaeologists excavating Jericho clear the top of a tower believed to date back to 7000 BCE. (Bettmann/Corbis)

It is important to stress that there is no simple trajectory toward larger and more complex villages throughout the Near East over this period. Indeed, the subsistence systems of some of the largest villages seen in the region before the development of large cities and towns after 4000 BCE were not based upon domesticated plants at all. Technically, these peoples are considered sedentary hunters and gatherers. In some parts of the Near East, these large villages were followed by the creation of a large number of smaller village sites. Although some archaeologists have argued that environmental collapse was responsible for the disappearance of these large villages, others have focused their attention on changes in subsistence patterns—full reliance upon plant and animal domesticates—that permitted village peoples to disperse into new ecological niches favorable to farming. It is thus best to think of the

ancient Near East as a mosaic of variability in village size, organization, and subsistence practice.

The earliest village sites in the ancient Near East are found in the Early Epipaleolithic period, which dates from 20,000 to 12,000 BCE. At this time, the inhabitants of the region were still hunters and gatherers who relied upon the abundance and availability of wild foods in the environment. Although most of these peoples were still mobile, one site in the Levant (in modern Israel), Ohalo II, reflects early sedentary life and the formation of a small village composed of a small number of domestic residences. The group that inhabited this site probably numbered no more than 50 people, but the site is distinguished by its permanence on the landscape. Although there are likely to have been small villages of this size elsewhere in the region, Ohalo II is the only one discovered to date.

In the following Late Epipaleolithic (12,000–9600 BCE), larger villages begin to appear in the region, especially in the Levant. The Natufian is the name of the archaeological culture here. Although there was considerable variability in the kinds of settlements present, what is important is the emergence of large permanent villages, such as Eynan, that may have been composed of 200–300 people. At Eynan, for example, the houses are relatively small circular structures that showed little variability. Subsistence in the Natufian culture reflects reliance upon stored plant foods, hunted animals, aquatic resources like fish and birds, and other seasonal plants. Although there is variability in the size of some of the structures at Eynan, there are no obvious ritual or large communal structures present.

The Neolithic in the Near East is divided into a number of periods, each of which shows interesting variability in village structure and organization. The so-called Aceramic Neolithic (so-named because of the absence of pottery) dates from 9600–6900 BCE and is divided into two periods: 9600–8800 BCE and 8800–6900 BCE. In the earliest of these periods, domesticated plants and animals have yet to dominate the diet. People were harvesting wild plants such as the abundant ancestors of wild wheat and in some cases cultivating these plants. However, their interaction with them at this time was not sufficient to change the structure and genetics of the plant into the domesticated variants we know today. But whatever the diet, villages, some of them relatively large, began to appear across the region. Although some villages continued to have circular buildings that were clustered together, other villages began to be based upon an architectural canon of rectangular rooms that adjoined one another to form large room blocks. At some villages, new structures that are clearly not residential are found, and these have been interpreted as communal rooms where religious rituals or other community-level activities took place. At many villages of this period, food storage, which is essential for survival, was organized at the community, not household, level. This suggests to some anthropologists that the inhabitants of these villages emphasized the importance of community over the individual household.

➤ ÇATALHÖYÜK—SOMETHING DIFFERENT IN SIZE AND COMPLEXITY

Çatalhöyük is one of the largest village sites of the Neolithic Near East and was occupied during approximately 7500–5700 BCE. First discovered and then excavated by Sir James Mellaart, the site is more than 32 acres (13 hectares) in size. The site is exceptional because of its size as well as the preservation of extraordinary art found painted on the walls of many of the houses. Estimates of population size range from 5,000 to 8,000 people. Although the large majority of rooms excavated to date are residential, or domestic, a number of rooms interpreted as shrines that may have served a communal purpose have also been discovered. Shrines are characterized by the display of decorated skulls of bulls that are prominently displayed on benches or embedded in the walls. Many of these rooms also have impressive murals that depict scenes of humans, animals, and geometric designs. Burials, often contained in baskets, are commonly encountered at the site and are found below the floors of many domestic residences. Human skulls covered in plaster are thought to reflect religious or ritual activities.

—Mark Aldenderfer

Bibliography

- Balter, M. *The Goddess and the Bull*. New York: Free Press, 2004.
- Hodder, I. *The Leopard's Tale: Revealing the Mysteries of Çatalhöyük*. London and New York: Thames and Hudson, 2006.

By the later part of the Aceramic Neolithic, most village communities were now fully reliant upon domesticated plants and animals for their diets, although their inhabitants continued to hunt wild animals and gather wild plants. Both large and small villages persisted across the Near East, but in some places truly extraordinary villages appeared. Examples include Çatalhöyük in modern Turkey, Jericho (in the Jordan Valley), and 'Ain Ghazal in Jordan. These villages were very large, with thousands of inhabitants. The constructions were solid and impressive as well and included rooms for habitation, ritual activities, and other functions. These very large sites were something very different and were likely

to be important regional centers for political and social interaction in the regions in which they are found. Also of interest during this period is the gradual shift from communal storage of food to household-based storage. Although community remained important judging from the presence of ritual and community structures at many sites, this shift in storage of subsistence goods suggests that individual households were becoming more self-sufficient.

The Ceramic Neolithic (6900–6000 BCE) marks a fundamental transformation of village life in the Near East. All of the very large villages that appeared in the preceding period now disappear and are replaced by much smaller villages that move into a number of distinctive ecological niches. These smaller villages are likely composed of self-sufficient households. This pattern of village formation persists into the following Chalcolithic period (6000–3000 BCE). However, this is a period of dramatic political and social change. By the end of this era at 4000 BCE, villages are now a part of the much wider network of large towns and emerging urban centers that will flourish after this date in much of the Near East.

Early Village Life in Ancient India

The time around 10,000 BCE is one of the most significant in human history. This is when humans left behind their prehistoric past and embraced new lifeways. During this time, South Asia and much of the rest of the Old World was in the terminal Mesolithic phase of prehistory, dominated by microlithic assemblages. Subsistence economy was still largely based on hunting, fishing, and gathering but had become highly specialized as compared with the earlier

Paleolithic phase. The majority of Mesolithic groups lived at open-air sites, although a large number of caves and rock shelter complexes have been documented from various parts of the Indian subcontinent (e.g., Bagor, Langhnaj, Bhimbetka rock shelters, Sarai-Nahar-Rai). It is culturally significant that during the Middle Holocene and later in India, Mesolithic or hunter-gatherer groups (i.e., tribal populations), Neolithic groups, and the Chalcolithic phase chronologically and spatially overlapped in various parts of the subcontinent. Even during early historical times and up to modern-day times, there were economic interactions between the forest/hill-dwelling tribal groups and the nontribal inhabitants of agricultural villages and towns and cities. The planned production and domestication of rice, wheat, and barley was in sync with the domestication of cattle, buffalo, sheep, goats, pigs, fowl, and dogs (animal husbandry and pastoralism). During the Neolithic, handmade pottery was more prolific than wheel-made pottery, which became dominant later. The Neolithic economy was a combination of plant cultivation, animal husbandry, and hunting-gathering. The recovery of a respectable amount of querns and grinding stones from numerous sites testifies to the advent of increased and regular food production. This, in turn, resulted in a decrease of nomadic lifestyles and an increase in seasonally sedentary settlement or establishment of villages.

One of the most important South Asian typesites for incipient village life is Mehrgarh (Pakistan) and represents the earliest evidence of plant and animal domestication in South Asia. Its pre-Harappan cultural roots originated in West Asia from where Neolithic groups dispersed into other regions, but its subsequent development appears to be indigenous. Occupational levels start at about 6500 BCE, when farmers cultivated and exploited wheat, barley, peas, cotton, dates, and sesame seeds and raised cattle, sheep, and goats. Divided into seven periods of development, the earliest does not contain any pottery, which seems to appear at about 5500 BCE at the site. The next two periods are Neolithic with ceramics, and the last four can be attributed to the Chalcolithic phase with an increase in specialized artifact production. Houses were made of mud and mud bricks, and different

types of artifacts have been recovered: ornaments of bead, shell, and turquoise (representing long-distance transport); terra-cotta and bone seals; stone and copper drills; stone sickle blades in bitumen; bone points; awls; stone blades; kilns; and crucibles for melting copper. Flexed burials have been found here (under house floors) with ochre, grave goods (e.g., ornaments such as steatite-bead necklaces, ground axes, baskets), and animal bones. The site represents one of the earliest that had a direct influence on the subsequent birth of the Harappan civilization. While Mesolithic sites were generally homogenous, the Neolithic phase was the first to accommodate cultural variation at a sub-regional level. South Asian Neolithic sites and associated material culture can be archaeologically separated into several broad geographic groups, and all are highly distinct from each other. In southern India, well-known Neolithic ashmound sites (accumulation of burnt cow dung) include Budihal, Sangankallu, Piklihal, Tekkalakota, and Utnur. In Kashmir Valley, this phase is best represented by the pit dwellings in Pleistocene loess deposits such as at Burzahom and Gufkral, where steps down into the pit floors were cut in the walls of the structures (into Karewa deposits). Unlike other Indian Neolithic sites, the Kashmir Neolithic shares a few features with some Chinese sites. During the fifth to fourth millennia BCE, Neolithic populations in Baluchistan had started migrating to the north and east, some gradually giving rise to the Chalcolithic in central and northwestern India.

At many sites and regions the Neolithic phase is missing, and there is a direct stratigraphic transition from the Mesolithic to the Chalcolithic. Due to accelerated agriculture and shifting cultivation, alluvial plains were increasingly favored for settlement. This trend of village-level settlements is archaeologically visible through the following regional Chalcolithic cultures: Ahar (e.g., Gilund), Malwa, Kayatha, Jorwe (e.g., Daimabad), the Ochre Colored Pottery (OCP) culture, Savalda (e.g., Kaothe), and the Narhan culture. It is thought by many scholars that evidence for the religious roots of modern Hindu society are reflected in Harappan and Chalcolithic phases. Architecture progressed from simple wattle-and-daub houses to mud and mud-brick houses; later,

stone was also utilized. Hut and house shapes ranged from circular, square, and rectangular to oval, often with compact mud floors. Fortification at many sites was initially thought to represent warring or feudal societies, but this interpretation is being rejected by some scholars. The second half of the Holocene also witnessed a major spurt in the variety of pottery styles and associated motifs. The role of granaries with pits and/or large ceramic jars highlights the increase and importance of food storage, which revolutionized the modes and scales of economic agriculture (i.e., trade with regional and distant counterparts). Surplus food production (e.g., millet) also led to individual technological and artistic creativity, including craft specialization and domestic construction. This inevitably led to the establishment of hierarchical societies whereby different levels of economic contributions became the norm. There was rapid improvement in the technological and methodological efficiency of agricultural practices (e.g., irrigation). The appearance of copper and bronze marks the onset of metallurgy and associated production of a rich repertoire of tools and implements for everyday life. Regional centers with small satellite villages developed in the form of farmsteads, hamlets, campsites, craft-production centers (bead manufacture or salt processing), and so forth. Such growing economic prosperity led to an increase in villages and subsequently towns and cities. These early villages (e.g., Inamgaon, Navdatoli) became the cultural foundations of modern-day Indian rural life and, with the exception of external influences and modern technology, have changed only marginally since then.

Early Village in Ancient China, 10,000–5000 BCE

There is much speculation about the social life and the family structure of the people who built the early village communities of ancient (Neolithic, 10,000–5000 BCE) China. The archaeological data is sparse, and all theories about what day-to-day human existence must have been like must be understood as open to debate. The most scrupulous scholars are careful not to project their own worldview upon prehistoric populations. We have nothing in writing from this period that would give insight into the emotions, thoughts, motivations, or experiences of individuals who comprised these communities. However, archaeologists have uncovered man-made artifacts and botanical remains that give insight into the material culture of Neolithic settlements and some hints as to social life. If we are conservative in our extrapolations, we may state a few facts.

Humans inhabited both caves (usually on the seacoasts, sometimes inland) and clusters of free-standing houses near water sources (rivers and lakes) in Neolithic China. One sort of shelter was not superseded by the other. They coexisted and exploited different ecological environments. Seacoast caves sheltered those populations who harvested the products of seas and oceans, while people who built subterranean “pit dwellings” (wattle and daub walls, thatched roofs) along the inland rivers and on the banks of lakes fished in these freshwaters, hunted land animals, and eventually began to plant seeds and breed animals to serve human needs more efficiently. In southern China—which was subject to severe flooding that nonetheless ensured fertile soil, as the flooding of the Nile did in ancient Egypt—pile dwellings (houses raised above water by means of wooden posts) allowed for this environmental hazard. Social and economic changes that followed such ecological adaptations were gradual, and one lifestyle did not oust another; however, variations occurred according to climate and environment.

One common misconception is that the appearance of pottery only coincides with Neolithic plant cultivation and the appearance of sedentary communities. However, at the Chinese cave site of Miaoyan (Guangxi), pottery predat-

ing 10,000 BCE was found. At the open-air camp found at Nanzhuangtou, although no domesticated plants or animals were found, low-fired incised sherds are dated to between 9000 and 8000 BCE. Human existence predating 8000 BCE was most probably nomadic; therefore, it seems that the manufacture of pottery does not necessarily require sedentary existence, nor do communities of pit dwellings necessarily indicate a sedentary lifestyle. A seminomadic rather than a completely sedentary existence seems to have been most characteristic of the Neolithic cultures of China, for pollen analysis of plant matter and the bones of deer and wild boar found at Neolithic sites suggest that wild plants and wild game continued to augment food supplies of domesticated millet (northern China), domesticated rice (southern China), and domesticated cow, chicken, dog, and pig by 7000 to 5000 BCE.

The problem is that we do not know who occupied the Neolithic settlements at various times of the year or for what length of time. We do have a basis of comparison, however. Native American indigenous populations who were seminomadic foragers and horticulturalists occupied their villages only from spring to summer to plant and then to harvest their crops. During the winter months entire villages (men, women, and children, all except the very elderly or the very ill) traveled into the wilderness to follow wild game. For this reason, colonial authorities of historic times often characterized Native American villages as “abandoned” when they were only unoccupied for a brief three to four months out of the year.

Early village life in China could have followed a similar pattern. Another possibility is that women, children, and frail elderly persons may have been left behind while the men alone hunted and fished at great distances from their habitations, but we have no absolute proof of this division of population into sedentary and traveling occupations based on gender, age, or fitness, nor do we know if both men and women farmed and engaged in animal husbandry or if gender dictated economic role. In addition, we do not know who made the pottery and tools: men or women or both. The most likely scenario is that early village life was egalitarian, based upon mortuary practices.

In terms of mortuary practices and living arrangements, the Peilingang site in Henan Province (6500 to 5000 BCE) offers one of the most complete assemblages of artifacts and botanical remains for describing village life in ancient China. At this site were discovered 48 semisubterranean dwellings, 300 storage pits, pottery kilns, chipped and ground stone tools including sickles for harvesting domesticated millet, bone flutes attesting to musical development, turquoise jewelry, and other sorts of adornment as well as 300 burials in formal cemeteries where the dead were interred with grave goods to serve them in the afterlife. One indication that Neolithic village life was egalitarian is that the graves were roughly equal in size and equal in the amount and the quality of the grave goods. One of the most interesting finds at the site was incised turtle shells filled with small pebbles, which may indicate the development of shamanism and divinatory arts. At the site of Yangshao (5100 to 5000 BCE) archaeologists found that hemp was pressed for oil and used to manufacture clothing. Ceramic spindle whorls for spinning thread were also found.

By 5000 BCE the archaeological record indicates social change. There seems to have been a population explosion, for communities of permanent dwellings proliferate. Graves are no longer of equal size, and there is differentiation in the amount and quality of grave goods, indicating the development of social hierarchies. There is also evidence of warfare that may have been due to the coveting of accumulated wealth, or it may indicate social pressures such as overpopulation that led to conflict over land. There is also evidence that health declined for Neolithic peoples due to several factors. Diseases were more easily spread when people lived in closer proximity to one another. Living with domesticated animals and their excreta may have increased disease. Also, diet became more restricted when Neolithic people ceased to forage and hunt.

Early Village Life in Europe

The introduction of agriculture changed the way the peoples of Europe lived and interacted with their environments. Contrary to the popular notion of an agricultural revolution, which implies a rapid change, the transmission of agriculture across Europe was lengthy and uneven due to factors such as climate, geography, and local traditions. Starting from its introduction in about 7000 BCE, it took more than three millennia for agriculture to become the primary means of subsistence throughout Europe. From its origins in western Asia, agriculture spread in two general directions across Europe. Colonists from the southeast took agricultural technology to the eastern Mediterranean islands and then on to Greece, Italy, and westward. A second movement of agricultural technology spread from the southeast Balkans up through central Europe and eventually to France and the British Isles. By the fourth millennium BCE, indigenous Mesolithic hunting and gathering practices had given way to sedentary Neolithic agrarian villages.

Some of the oldest evidence for agricultural life in Europe comes from Franchthi Cave in the northeastern Peloponnese of Greece, where around 7000 BCE Mesolithic hunting and gathering activities were supplemented by the cultivation of emmer wheat and barley and the raising of sheep and goats. As this occurred, the focus of daily life moved out of the cave to the surrounding area. The presence of obsidian from the Aegean island of Melos indicates trade with the eastern Mediterranean and perhaps the source of the agriculture, domesticated animals, and pottery enjoyed at Franchthi Cave. As often occurred in this transitional phase, populations increased with the introduction of agriculture and a sedentary lifestyle. When populations increased beyond the land's capacity to sustain the

numbers or when crops failed due to drought or pestilence, portions of the population moved on to new territories, taking their agricultural and animal husbandry skills with them.

Between 7000 and 5500 BCE, settlements were established in northern Greece that reveal much about early village life in Europe. Communities consisted of groupings of square or rectangular wood-framed houses, some reaching 39.3 feet (12 meters) long. The typical interior consisted of a single room, with a clay oven on one wall and a stone floor. The exterior walls were covered with clay or daub, and some were painted. The houses appear to have held individual families, and their close proximity to one another indicates the importance of the community and cooperation. At Sesklo, in northern Greece, some houses contained basements, and others had two stories.

At settlements such as Nea Nikomedeia in Macedonia, the houses were grouped around a larger central building, perhaps used as a shrine or a meetinghouse. With the absence of writing, little is known about the spiritual lives of early Neolithic villagers. Across Europe, the presence of figurines of both females and animals indicates that fertility and nature were of central importance. As time passed and settlements spread northward and westward, the size of the villages increased, as did the size of the individual houses and meetinghouses, but overall populations remained small due to the limitations of early farming techniques and local resources.

Within these Neolithic villages, daily life consisted of tilling, planting, tending, and harvesting the fields along with the feeding and caring of livestock. In addition to growing wheat and barley and raising domesticated sheep, goats, pigs, and cattle, the villagers searched for wild plants such as berries, fruits, and nuts and hunted wild deer, small game, and birds. Archaeologists speculate that hunting may have been relatively easy, as many wild animals and birds would have been drawn to the cultivated fields near the villages.

With the availability of plant, animal, and natural resources, early villagers would have had a wide array of foodstuffs and materials. With grain, they made breads and gruel. Wild honey and fruit may have been used as sweeteners.

The animals produced milk and supplied meat and hides. The hides were used for clothing and blankets. Animal bones were used for making tools, fishing implements, and sewing needles; animal sinews were used for threads. Cutting tools and weapons were created out of obsidian and flint, and stones, shells, and copper were used to create jewelry and ornaments.

The introduction of pottery served to protect food supplies from pests and the elements. Early pottery was made by hand without the use of a pottery wheel. The earliest pottery was plain, but eventually villagers began painting and incising decorations on pottery. The spread of agriculture can often be traced by the presence of certain types of pottery at various sites. The Bandkeramik culture, named for its linear bands or incisions of its pottery, stretched from Hungary to France. Pottery designs may have been purely aesthetic, but they may have also indicated the owner's status in the community or the community's distinctness from other communities. Pottery that is fragile or easily broken is indicative of a sedentary way of life and is found throughout Neolithic Europe.

The burial practices of the early villagers varied by time and region, but all reflect a respect for the deceased. Infants were sometimes buried within the dwelling itself, often near or under the hearth, whereas neonatal infants and newborns were placed in the graves of their mothers, who presumably died in childbirth. Adult burials were typically placed close to the dwellings. Males were buried with tools and females with jewelry, reflecting their roles in life and perhaps indicative of a belief in the afterlife. As societies became more stratified, class distinctions were reflected in burial practices, as in the monumental mortuary mounds found in France and the British Isles.

The adoption of agriculture changed the societal face of Europe. Mesolithic hunting and gathering practices had been an extension of the natural and animal world, with humans living in balance with nature and each other. Agriculturalists, on the other hand, sought to alter and control nature. Village life focused on production and accumulation, which led to wealth and power stratifications within those populations. By 4000 BCE, the societal and en-

vironmental landscape of Europe had been changed forever.

Migration and Travel

At the start of this era, our most distant ancestors lived in a very small region of East Africa. By its end, humans had spread across the globe and had taken up residence in virtually every corner of the planet and were now living in arid deserts, high plateaus, deep tropical forests, and frigid tundras. The only places on the planet that our species has never occupied, at least until very recent times, are Antarctica and Greenland.

The story of our ancestors' travels is really a story about adaptation and the movement of our ancestors in and out of ecological niches. Although it is romantic to think of a small band of *Homo erectus* moving steadfastly out of Africa and into the Middle East and then ultimately into East Asia, the reality is that the distance moved by any band of our ancestors was likely to have been very short. The motivation to move was not a predisposition for wanderlust but instead was the necessity to eat and to feed the members of the group. Our ancestors had no way of knowing that East Asia lay thousands of miles to the east; they were only concerned with ensuring a steady diet. In this way, our ancestors were much like the many other animal species that moved across the globe throughout the Pleistocene and into the Early Holocene.

The constraints on the movements of our ancestors were numerous. Environmental conditions and resource availability were the most important. During much of the glacial era of the Pleistocene, many areas of the world simply did not have sufficient resources to support even small groups of people. A secondary constraint related to this was the relative simplicity of the technologies of our early ancestors. In very cold environments, clothing and the controlled use of fire are absolute necessities for survival. However, clothing suitable for very harsh environments did not appear until between 70,000 and 45,000 years ago. Our ancestors appear to have controlled fire possibly as early as 400,000 years ago. Depending on the severity of the climate, this means that our ancestors were unlikely to have migrated into the highest northern latitudes, highest mountains or plateaus, or other cold marginal environments until fairly late in our history.

The cognitive capacity of our ancestors may also have been a serious constraint on the migrations of our ancestors. One of the hallmarks of our own species is the degree to which we can plan complex moves into the future. Modern hunters and gatherers in the Arctic, for example, look at least six months into the future and examine multiple possible residential moves before deciding upon their course of action. Choosing the wrong set of moves could lead to the death of all members of the group. This ability to look into the future is known as anticipatory

planning. This ability is especially important in harsh resource-limited environments. It seems that *Homo erectus* was the first of our ancestors to have sufficient cognitive ability to move over longer distances and into unfamiliar environments, as is witnessed by the spread of the species out of Africa and into the East. Since *H. erectus* did not move into more northerly latitudes, this suggests that planning in depth was not a part of the behavioral repertory of this species.

The very large majority of the migrations of our ancestors were by foot. However, there are a number of examples of migrations that were at least in part accomplished by some sort of watercraft. The peopling

It seems that Homo erectus was the first of our ancestors to have sufficient cognitive ability to move over longer distances and into unfamiliar environments, as is witnessed by the spread of the species out of Africa and into the East.

of the New World is a good example of this. Until relatively recently, it was believed that the entire New World had been populated by foot-mobile people moving across the Bering Straits land bridge and ultimately moving into both North and South America. Recent studies suggest that there was very likely a movement of people down the western North American coast. This could only have been accomplished with the use of some sort of

watercraft, most likely some sort of skin boat like a coracle. A more controversial idea has people from Europe moving into the northeastern coast of North America. Demonstrating these possible migratory routes is difficult, however, because ancient shorelines are now inundated by ocean waters following the rise of sea level that followed the melting of the ice sheets at the onset of the Holocene.

Population movements or migrations appear to have become more frequent after our species became dependent upon domesticated plants and animals for our subsistence. Sedentary peoples have higher population growth rates than do mobile peoples, and this combined with the development of a more stable subsistence system led to a population explosion in some parts of the world, such as the ancient Middle East. Absolute population size increased, as did local population density. Populations can continue to grow as long as there is sufficient agricultural land to support them. However, as land becomes scarce, people must either create new subsistence technologies to support this larger population or move to new areas where land is available. Other factors that promote group movement are social in nature. Villages that grow too large tend to have more conflict between members of rival lineages or families. In the absence of some kind of widely recognized central authority, such tensions make it likely that some set of families will move to a new area simply to escape these problems.

The contributions in this theme explore these topics in greater detail and provide insight into the multiple ways in which our ancestors moved across the globe.

—Mark Aldenderfer

■ Introduction: Out of Africa—The First Time

The first of our ancestors to leave their African origins is widely believed to be *Homo erectus*. This species, which originated in East Africa, is thought to have first migrated out of Africa between 1.6 million and 1.8 million years ago and quite possibly far earlier. Although the specific routes of its dispersal are unclear, it moved from Africa into the Near East, western Asia, and eventually Southeast Asia. There is no evidence of movement of *Homo erectus* into Europe or central Asia, and evidence for its presence in East Asia is equivocal at best.

The stone tool assemblages carried by these hominins were composed of a core and flake technology similar to that seen in East Africa and known as the Oldowan. There are numerous tool assemblages found in the Near East and West Asia that are likely to be made by *Homo erectus* but are not directly associated with fossil specimens. Although these stone tools are found in Southeast Asia, there are fewer sites when compared to other areas.

Variability in skeletal morphology of *Homo erectus* suggests that more than one group of this hominin migrated from Africa. This is no surprise, in that the total population size of the migrants was likely to have been very low and the groups widely dispersed. This would have meant that mating networks would also have been small, and this in turn means that genetic diversity was likely significant.

One of the most interesting questions about this migration from Africa is why it happened in the first place. At this time, a number of species began to expand out of Africa and into other nearby regions. However, these species moved as their ecological niche expanded. In contrast, although some of the movement of *Homo erectus* was indeed within the ecological niche within which it evolved in Africa, as it moved into West and Southeast Asia it encountered different niches and adapted to them successfully. Undoubtedly, this reflects the growing cognitive capacity of this hominin and its ability to use culture as its primary means of adaptation.

Although most paleoanthropologists have accepted this reconstruction of the past, it is not

without controversy. Some have argued that *Homo erectus* was not necessarily the first hominin species to leave Africa and have suggested that it was one of the australopithecines or possibly *Homo habilis* or a more primitive version of *Homo erectus*. However, careful analysis of the known fossil evidence indicates that *Homo erectus* was indeed the first of our evolutionary lineage to leave Africa.

The Adaptive Radiation of *Homo erectus*

Homo erectus was the first hominid to move out of Africa and disperse into Eurasia. Its large-scale migration represents the first major adaptive radiation in human evolution. This radiation was relatively rapid, because the earliest Indonesian fossils are about 0.5 million years younger than the earliest African fossils (ca. 1.8 million years ago). Migration was inherent to the nomadic lifestyle of *Homo erectus*, which kept them constantly on the move. The pattern of migration suggests that a coastal route was followed to reach the islands of Southeast Asia, which were then connected by a large land bridge, followed much later by a land-inward migration resulting in the colonization of the mainland. This movement resulted in a vast distribution of the species over a variety of landscapes and climatic zones with one major limitation: *Homo erectus* is found only in open landscapes and savannas. A population with such a wide range naturally shows regional differences.

The Asian homeland of *Homo erectus* extended from the Republic of Georgia on the Eurasian border to China in the northwest and Indonesia in the southeast. The climate and the

► THE GENETIC EVIDENCE FOR A COASTAL MIGRATION INTO SOUTHEAST ASIA

While scientists have for some time recognized that humans originated in Africa, some controversy has raged over the migration route taken as they left their homeland to colonize the rest of the earth. Some proposed a path from the lower Nile Valley across the Sinai Peninsula to the Levant. Others suggested a southerly path from the Horn of Africa and along the coast of Arabia and India into Southeast Asia and Australasia.

Fossil data to support either hypothesis has been difficult to come by—with the exception of coastal settlement of Eritrea about 125,000 years ago—but analysis of genetic data from indigenous populations in Southeast Asia and in the Andaman and Nicobar islands has provided the answer. An examination of the Orang Asli (original people) of Malaysia shows that their mitochondrial DNA

(mtDNA) lineages are quite distinct from that of other inhabitants of Southeast Asia. The analysis further suggests that the lineages date to between 44,000 and 63,000 years ago.

Analysis of the mtDNA lineages from the Andaman and Nicobar islands shows that the Andaman islanders likely represent an ancient colonization about 50,000 to 70,000 years ago, while the Nicobar islanders descend from much more recent immigrants. Data from Papuans and Aboriginal Australians indicate a similarly ancient origin. The coincidence of data—along with analysis of data from other Eurasian populations, who appear to have branched off from southern groups—further supports a purely southern route for *Homo sapiens*' initial exodus from Africa.

—David M. Lawrence

landscape were thus far from homogeneous. These variations in ecological parameters triggered local variations in the morphology and adaptation of *Homo erectus*. Furthermore, regional isolation on the islands may have further facilitated a diversification in the Asian *Homo erectus* population. Gene flow was probably limited within each island, as well as between the islands. The population on the mainland was divided into smaller units as well. The most northern sites, Zhoukoudian and Nanjing, were only occupied during interglacial periods. The glacial periods likely made the northern localities too cold or unreachable for *Homo erectus*. The relation between the South Asian population (Narmada fossils) and the other Asian populations is as yet unsolved.

The earliest migration into Java (Indonesia) took place about 1.2 million years ago. Fossils of *Homo erectus* are part of the Cisaat fauna. This fauna includes carnivores and is thus direct evidence for a land bridge connection to the mainland. *Homo erectus* thus reached the island by land and not by sea. After that, the island became isolated due to a rise in sea level. The fauna also became impoverished with endemic elements, such as a dwarf stegodon. *Homo erectus* fossils from Trinil (ca. one million years ago) be-

long to this insular period. Apparently, no new colonization took place for a long period, and *Homo erectus* evolved regional characters such as a relatively large skull, as evidenced by Ngandong material (200,000 years ago). Eventually, around 120,000 years ago, a land bridge developed through which a tropical rain forest fauna migrated into the island, known as the Punung fauna. It included a newcomer: *Homo sapiens*. Elements from the earlier fauna went extinct and with them *Homo erectus*.

The migration of *Homo erectus* into China took place considerably later than into Indonesia. The earliest evidence comes from Gongwangling in the Lantian Valley, dated to 800,000–750,000 years ago. *Homo erectus* fossils and stone tools have not been found outside the eastern half of China. They reached the northernmost sites (Zhoukoudian, Jinniushan) not before 500,000 years ago. The last occurrence is at Hexian (240,000 years ago).

Zhoukoudian was utilized during more temperate climatic periods of the interglacials. The stratigraphy of the site and the sequential layering of the occupational layer argues for sequential use of the area by *Homo erectus* and against a single interglacial occupation. There is no evidence that the site was frequented during glacial

periods as well. The combined range of dates for the southernmost located sites Yuanmou and Hexian (600,000–240,000 years ago) includes both glacial and interglacial periods. Here, *Homo erectus* was not on the move but instead settled for a long continuous period of time.

In spite of early studies, an Asian morphotype does not exist. The mutual differences between the Asian specimens are too large to appoint one of them as a model for the Asian *Homo erectus*. In most studies, the so-called Asian morphotype is based on the skulls from Zhoukoudian in China, but these differ significantly from other Asian skulls.

Features of the skull point to the existence of two major geographic variants of *Homo erectus* in Asia. The first variant comes from Indonesia and is quite consistent through time. The earlier and the later Indonesian skulls are more similar to each other than to the second variant except for their size. The observed differences between early and later forms are entirely size-related. The second variant comes from northern China and is in time and size intermediate between the early and latest Indonesian specimens. The Indonesian variant has a wide posterior vault and a relatively broad occipital region, compared to the northern Chinese variant. The most prominent differences are that the Indonesian faces are more prognathic than the Chinese faces and have larger front teeth and more massive molars. The Georgian skulls and early African skulls seem to follow the Indonesian variant.

Whether the southern Chinese forms follow the second variant is not clear, because the specimens are either too fragmentary (Yuanmou) or too deformed (Gongwangling). The specimens from Hexian differ somewhat from the northern Chinese variant and from the Indonesian variant as well. This observation indicates that a geographic variation may indeed have existed in China, probably triggered by latitudinal adaptation. The north-south variation then reflects the adaptation of the northern variant to colder regions.

The variation in form observed among the earliest Indonesian skulls is larger than that observed among the Chinese and later Indonesian

skulls. Features observed in the later skulls are present in the early skulls but not always so vice versa. It appears that each of the later groups preserved and elaborated different aspects of the earlier forms.

The contact between the Chinese and Indonesian variants of *Homo erectus* during the Pleistocene was most of the time hampered by high sea levels, which submerged the land bridge connections between the islands and the mainland. Another blocking factor was environmental factors on the mainland that were related to the ice ages. During glacial periods, the northern regions of the mainland were not inhabited, and likely *Homo erectus* migrated farther south, into the contact zone with the land bridges.

A Failed Migration into Europe by *Homo antecessor*

Homo antecessor is a putative hominid species whose fossilized remains are some of the oldest evidence of human occupation of Europe. The species is known from only two locations, the Gran Dolina and Sima del Elefante sites, both in the Sierra de Atapuerca of northern Spain. Specimens attributed to *H. antecessor* date from the Early to Middle Pleistocene, 1.2 million to 800,000 years ago.

The species is a controversial one. Some of the controversy is over whether the species is a valid species or whether it may represent a

chronospecies, a transitional stage along the evolutionary path from one species to another. Part of the problem in assessing its status is the relatively small number of specimens and the restricted region from which it has been found. Another problem has been that some of the best-preserved specimens are juveniles, but many of the diagnostic characteristics of the hominid line are only visible in adult specimens.

Another controversy is over the place of *H. antecessor* in the hominin evolutionary sequence. The species was originally proposed as an intermediary between *H. ergaster* (which is either a separate African species or an African variant of *H. erectus*) and *H. heidelbergensis*, a possible ancestor to both modern humans and Neanderthal man (*H. neanderthalensis*). Some researchers argue that *H. antecessor* is the same species as *H. heidelbergensis* (the latter's status as a species is also somewhat controversial).

Whatever *H. antecessor*'s status as a species, it raises questions about the origins of the first Europeans. The prevailing assumption has been that the first hominins came to Europe from Africa via Southwest Asia. Early analysis of jawbone characteristics seemed to confirm that *H. antecessor* had African ties, with *H. ergaster*/*H. erectus* being the most likely ancestor. More recent comparisons of the characteristics of *H. antecessor* teeth to those of Pleistocene species from Africa and Asia suggest, however, that the influence of Asia (via *H. erectus*) on the hominin colonization of Europe was greater than the corresponding influence of Africa.

The question of whether *H. antecessor* evolved elsewhere and migrated into Europe or whether it evolved in Europe from an earlier migrant remains unresolved, although a European origin seems more likely.

Whatever its origins, *H. antecessor* was a toolmaker from the start. The Sima del Elefante site, where its oldest fossils have been found, includes knapped stone objects and stone flakes, evidence of tool-making activity within the cave itself. More layers of stone tools are found at the Gran Dolina site.

H. antecessor was a hunter or at least a scavenger. Bones of large mammals within the Sima del Elefante and Gran Dolina sites have cut

and scrape marks that are clear evidence of butchering. Butchering was not limited to animals, however. *H. antecessor* remains at the Gran Dolina site likewise show evidence of butchering. Given that the butchered hominin remains are scattered among the animal remains rather than stored in a separate place, it appears that the motivation for cannibalism was solely for food.

H. heidelbergensis Moves across Africa into the Middle East and Europe

Homo heidelbergensis, or Heidelberg man, is a hominid species whose fossilized remains, along with those of *H. antecessor*—which may be the same species—are some of the oldest evidence of human occupation of Europe. The species, like its predecessor *H. erectus*, spread far beyond the African continent, ranging across Eurasia from eastern China to western Europe.

Specimens attributed to *H. heidelbergensis* date from the Early to Late Pleistocene, 1.2 million years ago (if *H. antecessor* and *H. heidelbergensis* are two variants of the same species) to about the time of the appearance of modern humans (*H. sapiens*) about 200,000 years ago. The

better-documented specimens of *H. heidelbergensis* range from about 800,000 years ago to 200,000 years ago.

Since the species was first described from a mandible (jawbone) discovered in a quarry in Mauer (near Heidelberg), Germany, its status as a species and its position in the hominin evolutionary tree have been uncertain. For a time, it was lumped with *H. erectus*, probably the first hominin to make a successful foray out of Africa. Some argued that it was an archaic form of *H. sapiens*. Since the discovery of *H. antecessor*, scholars have debated whether it and *H. heidelbergensis* are the same, though more recent scholarship tends toward the belief that the two represent separate species. Furthermore, some African specimens of *H. heidelbergensis* are assigned by some researchers to a different species, *H. rhodesiensis* (Rhodesian man).

Given the confusion over Heidelberg man's status as a species, it should be no wonder that there is likewise confusion over its position in the hominin evolutionary sequence. The prevailing hypothesis is that *H. heidelbergensis* is a descendant of *H. ergaster* (which itself may be nothing more than an African variant of *H. erectus*). It either evolved directly from *H. ergaster*/*H. erectus* or from *H. ergaster*/*H. erectus* via *H. antecessor* (which is less likely).

H. heidelbergensis appears to be the common ancestor of Neanderthals (*H. neanderthalensis*) and modern humans (*H. sapiens*), with a European population of *H. heidelbergensis* giving rise to the Neanderthals and an African population giving rise to modern humans. Many who accept the existence of *H. rhodesiensis* as a separate species believe, however, that *H. heidelbergensis* gave rise to Neanderthals only, while Rhodesian man gave rise to modern humans.

Heidelberg man most likely originated in Africa and spread from there to Europe and East Asia via Southwest Asia. The species brought with it Acheulean technology—oval and pear-shaped hand axes—that was developed in Africa and then spread across Eurasia as *H. erectus* colonized the Old World. Its tool-making skills indicate the capacity for symbolic thought and language.

There is other evidence to support Heidelberg man's capacity for symbolic thought and language. Dental wear indicates that *H. heidelbergensis* was predominantly right-handed, as modern humans are today. This supports the notion of brain specialization necessary for advanced thought and communication. Analysis of the outer and middle ear anatomy of several specimens from the Sierra de Atapuerca of northern Spain indicates that they had a similar sensitivity to sound that modern humans do, strong evidence of their capacity for spoken language.

H. heidelbergensis, like many hominin species, was a hunter. Substantial evidence of butchering of animal carcasses can be found at sites associated with Heidelberg man. Wooden spears found in a bog near Schoeningen, Germany, date to 400,000 years ago. Remains of wild horses found along with the spears show signs of butchery. It is likely, though not certain, that *H. heidelbergensis* was the hunter. Finally, one of the most famous Heidelberg man sites, the Boxgrove Quarry site in southern England, has an abundance of stone and bone tools along with remains of animals with many cut marks, revealing evidence of butchery.

■ Introduction: Out of Africa—The Second Time

Transitional or anatomically modern *Homo sapiens* appeared in Africa some 200,000 years ago, and by roughly 15,000 years ago the species had migrated to all of the continents of the planet excluding, of course, Antarctica. In this process, they moved into very different environments, including high plateaus, deserts, islands, and cold dry steppes. Although *Homo ergaster/erectus* had left Africa much earlier, this species remained in relatively benign environments and did not move into the planet's more marginal places.

Until recently there has been considerable debate about the timing of this second migration and the number of times our species left Africa. New fossil discoveries as well as more detailed analyses of mitochondrial and Y-chromosome DNA, however, have led to a growing consensus on how to explain the second migration from Africa.

Although it was speculated that our species could have left Africa as early as 100,000 years ago, this date is now seen as far too early, and converging lines of evidence point to an initial migration out of Africa in the interval between 50,000 and 60,000 years ago. This later date means that we are looking at a behaviorally modern *Homo sapiens* that likely possessed language as we know it today.

The source location of these early humans is hypothesized to be East Africa. Not only did these ancestors move out of Africa, they also colonized southern Africa as well at least by 35,000 years ago if not far earlier. The migrants are believed to have moved out of Africa via a route that crossed the Red Sea and into the Arabian Peninsula. At least one other route out of Africa—via the Nile Valley into what is now the Levant—has been hypothesized, but data for this route have yet to be recovered.

From the Arabian Peninsula, humans moved along a coastal route along the Persian Gulf into coastal India, Southeast Asia, and ultimately what was then Sundaland and Australia. This migration could have been accomplished in as little as 10,000 years, which would bring humans to

Australia by roughly 45,000 years ago. According to some authors, like Paul Mellars citing Carl Sauer, a coastal route would have afforded our ancestors a fairly easy path because they would have been quite familiar with these coastal environments, in contrast to the diversity of habitats they would have encountered in movements into the interior of the continents.

Moving into the interior of the continents, particularly into higher northern latitudes, would have been much more challenging. Most of Europe as well as central Asia at 50,000 years ago was quite cold and dry, and moving into these places would have demanded new subsistence adaptations. Those of our ancestors moving into Europe would have had an additional challenge: the presence of Neanderthals. Nevertheless, humans entered eastern Europe by at least 45,000 years ago and moved steadily westward throughout the rest of Europe. Just where this population of migrants came from remains unknown, but the source is likely to have been somewhere in West Asia. The number of migrations into Europe is somewhat uncertain as well, but archaeological evidence suggests that two separate waves moved into Europe from this hypothesized West Asian source.

Humans also moved eastward into central Asia and eventually into Siberia, arriving there around 30,000 years ago. From here, other groups of humans began to colonize the Americas, at least initially by a coastal route, as early as 15,000 years ago. The exact source of these migrants remains much debated, but recent research suggests that coastal populations of North Asia and Japan may have been the homeland of these first Americans.

***H. sapiens* Moves across Africa and Beyond**

Charles Darwin is credited with the origin of the “Out of Africa” hypothesis in his book *The Descent of Man* (1871). Given the similarities among humans and the great African apes—in particular the chimpanzees, bonobos, and gorillas—Darwin argued that humans and apes shared a common ancestor and that the common ancestor would likely be found in Africa.

While there was no dispute that hominins left Africa and populated Eurasia once before—that species was *Homo erectus*—a long debate raged over the place of origin of modern man, *H. sapiens*. For most of the first 125 years after the publication of Darwin’s book, the fossil record, with hominin finds in Asia and Europe as well as Africa, confused the matter more than it helped.

The multiregional hypothesis suggested that modern humans arose throughout the Old World with local differentiation but with sufficient gene flow among regional populations to permit species-wide evolutionary change from *H. erectus* to *H. sapiens*.

The “Out of Africa” hypothesis instead calls for a relatively recent origin of *H. sapiens* in Africa sometime in the last 200,000 years, followed by an exodus from Africa across Eurasia (and eventually the Americas) beginning about 50,000 years ago. This was not the first exodus of modern humans from Africa—they appear to have settled in portions of what is now Israel about 120,000–80,000 years ago, for example—but there is no evidence that descendants of those earlier migrations persisted until today.

The tide of debate began to turn in favor of the “Out of Africa” hypothesis in 1987, when analysis of mitochondrial DNA—which is

handed down intact from mother to child—suggested that all humans today descended from a mitochondrial Eve who lived in Africa about 200,000 years ago. Analysis of Y chromosomal DNA—Y chromosomes are passed down intact from father to son—found a similar pattern, with all human males today descended from a Y chromosomal Adam who lived in Africa about 60,000 years ago.

Modern humans had been in Africa for nearly 100,000 years before their great migration off the African continent. Factors that may have played a role in their dispersal include possible population growth and rapidly fluctuating environmental conditions. Genetic evidence indicates dispersal of modern humans across Africa first.

The climate changes, along with dropping sea levels as vast amounts of water were locked up in the northern ice sheets, helped open up migration routes out of Africa into Southwest Asia.

By 60,000 years ago, small groups of humans began to leave Africa. A vigorous debate has raged over which migration route was used: a northern route from the Nile Delta across the Sinai Peninsula into the Levant (eastern Mediterranean) or a southern route from the Horn of Africa, across the Red Sea, and along the coast of the Indian Ocean into eastern Asia and, ultimately, Australia.

The northern route may seem more intuitive given the relative ease—at least physically—of crossing between Africa and Asia there today; however, archaeological and genealogical evidence indicates that modern humans reached Southeast Asia via the southern route faster than they passed through the Levant into Europe by the northern route. Beyond the initial crossing into Asia, there were more obstacles to face along the northern route. It primarily involved travel by foot and would require crossing major barriers, such as deserts and mountain ranges; coping with new climates, from tropical to temperate and eventually polar; and learning to survive in each of the new environments encountered.

The southern route along the Indian Ocean had the advantage of allowing rapid movement for long distances with few obstacles and without having to adapt to wildly different environments. The humans making the initial crossing

of the Red Sea into Asia would need some kind of boat or raft, and a boat or raft capable of crossing the Red Sea is equally able to travel along the shore of the Red Sea and cross the straits that separate the chain of islands linking Southeast Asia to Australia. The entire route is in tropical or subtropical environments similar to the ones they left in Africa, and they would find plenty to eat in the sea and adjacent shores.

Archaeological and genetic evidence indicates the southern route was the primary route—if not the only route—taken by humans leaving Africa. Modern humans had reached what is now Malaysia by 55,000 years ago, Australia by 45,000 years ago, and Tasmania by 35,000 years ago. In contrast, by the northern route *H. sapiens* had only reached the Levant—Israel and Lebanon—by 50,000 years ago and Europe by about 45,000 years ago. The early settlers of the Levant may have arrived via either the northern or southern route. In either event, the northern route proved a more significant barrier to migration than the southern route.

Small groups of humans began pushing inland from the Indian Ocean toward the interior of the Asian continent. The mountainous spine of the continent, which generally runs in an east-west direction, proved a major barrier to northward expansion, but those who reached East Asia could bypass the mountains and head north—into the Arctic and ultimately across Beringia into the Americas—and west into central Asia and ultimately Europe. Groups in Southeast Asia and Australia, having mastered the art of sailing, pushed into Melanesia and across the islands of the Pacific, eventually reaching as far as Easter Island and Hawaii.

Settlers of the Levant, no matter how they got there, could likewise expand eastward into central Asia, northward into the steppes of eastern and central Europe, and westward along the Mediterranean into western Europe. As in Asia, the Alps of Europe posed a major barrier to northward expansion, such that many settlers of northern Europe likely arrived from the east. The earliest settlers of what is now the British Isles likely crossed by land when low sea levels created land bridges across what is now the English Channel and the Irish Sea.

Homo sapiens Enter East and Southeast Asia

When modern humans (*Homo sapiens*) left Africa, they were destined to pass through territory that either was occupied by or had been occupied by other hominin species. *H. erectus* had been a presence in East and Southeast Asia for more than one million years but was probably extinct by the time modern humans left Africa. *H. heidelbergensis* may have reached China as well, but that species was likely extinct too.

Other hominin species survived. *H. neanderthalensis* occupied a wide swath of territory from western Europe into central and South Asia, including the Levant (eastern Mediterranean), the key region for any exodus from Africa via a northern route from the Nile Delta across the Sinai Peninsula into Asia. In what is now the island of Flores in Indonesia, a diminutive hominin, *H. floresiensis*, survived until as late as 12,000 years ago. It is possible that modern humans encountered this species as they colonized Southeast Asia.

With the profusion of hominin species, each with a stone tool technology, it can be difficult to assign sites to particular hominin species without fossil evidence that allows a positive (and unequivocal) identification or accurate dating that places the site at a time when no other hominin species could have been present. These problems have created significant confusion in resolving the questions of when and by what path modern humans reached East and Southeast Asia.

The northern route featured plenty of the plant and animal resources that a group of hunter-gatherers needed to survive. From the Levant, the route offered ready access to Europe and central Asia and from there south and east to the Indian subcontinent and north and east into Siberia, but deserts and east-west trending mountain ranges—such as the Himalaya—restricted access to South and East Asia.

A southern coastal route, from the Horn of Africa across the Red Sea and along the shores of the Indian Ocean had a number of advantages. It would have allowed rapid movement over long distances, featured relatively few geographic obstacles such as deserts or mountains, and offered people adapted to life along the seashore essentially the same environment—with plenty of food and other resources—along the entire path of the migration.

Intervening bodies of water, such as the Timor Sea between what is now Indonesia and Australia, would not pose much of a challenge to people already familiar with traveling on the ocean, as humans living along the shores of the Horn of Africa would presumably be. There would be little direct evidence of their travels, however. If any groups built substantial settlements along the coastal route, those settlements have since been covered by the seas that rose 200 to 300 feet (60–90 meters) once the Ice Age came to an end.

Despite the challenges in identifying and dating modern human archaeological sites, especially along the now-inundated southern route, patterns of genetic diversity and archaeological evidence (including unequivocal modern human remains) suggest that modern humans reached East and Southeast Asia primarily via the southern route. The great migration began between 75,000 and 60,000 years ago during the

most recent Ice Age, when low sea levels narrowed the expanse of water the migrant humans had to cross to reach Asia.

The migrant humans traveled quickly, covering nearly 7,500 miles (12,000 kilometers) of Indian Ocean coastline in a few thousand years. In keeping with their coastal migratory path, modern humans appear to have settled areas near water before moving to the interior of the continent. Greater genetic diversity in Southeast Asia than in surrounding areas of East Asia, Australia, and Oceania suggests that modern humans resided in Southeast Asia longer than in the neighboring regions. It also suggests that Southeast Asia served as the local source region for the migrants who dispersed into the surrounding regions.

This hypothesis is reinforced by the dates of archaeological sites in and around Southeast Asia. Modern humans reached what is now Malaysia by 55,000 years ago. One of the better-dated sites, Niah Cave in Sarawak, Borneo, dates to a minimum age of 46,000 years before present (and is probably older). Modern humans reached mainland Australia shortly after arriving in Southeast Asia. The Nauwalabila site in northern Australia was settled by 50,000 years ago, and Devil's Lair, in southwestern Australia, was settled by 48,000 years ago. Tabun Cave, on the island of Palawan in the southern Philippines, was occupied by 47,000 years ago.

Determining the settlement history of China is difficult because of confusion over taxonomy and dates. Many Chinese researchers embrace the multiregional hypothesis of human origins. As such, many of their older sites (older than 70,000 years, or prior to the accepted start of the migration from Africa) are attributed to "archaic" or "premodern" *H. sapiens*, though it is probable that those are actually other species, such as *H. heidelbergensis* or even late surviving *H. erectus*. The dates of many of those sites are questionable. Nevertheless, most of the sites attributed to "modern" *H. sapiens* in China range from 40,000 to 30,000 years old.

Dates for sites in Siberia, which was populated by migrants from the southwest (ultimately via the northern route out of Africa) as well as from the southeast (via East Asia) range from about 40,000 years ago in the south to about 13,000 years ago in the north. Modern humans

most likely reached Japan about 36,000 years ago and the Korean Peninsula about 30,000 years ago.

What Happened to *Homo erectus* in Asia?

Homo erectus disappeared around 400,000 years ago from the East Asian mainland. On the Indonesian islands, the species survived well into the late Pleistocene, up to 200,000 (on Java) or even 12,000 (on Flores) years ago. On the mainland, *Homo erectus* was replaced already much earlier by archaic modern humans and these on their turn by modern humans. There is no evidence that *Homo erectus* migrated into Australia. The oldest evidence for human occupation of Australia is around 50,000 years ago and is ascribed to *Homo sapiens*. As far as is known today, modern humans were not the direct cause for extinction of earlier *Homo* species in Asia. More likely, the disappearance of *Homo erectus* was driven by changes in the climate and environment. This disappearance may be either extinction or a gradual evolution into a more advanced form.

The end of *Homo erectus* and the beginning of *Homo sapiens* in Asia is still a matter of debate. At present, two opposite views prevail. One maintains that *Homo sapiens* evolved some-

where in Africa and dispersed into the Old World, replacing *Homo erectus* in Asia and *Homo neanderthalensis* in Europe (the uniregional model, the Recent Out of Africa model, ROA). The other maintains that *Homo sapiens* evolved more or less simultaneously from various regional variants of *Homo erectus* (the multiregional model, or MRE) through intermediate archaic forms. In the second model, no major migration of *Homo sapiens* and no replacement took place. In the first model, *Homo sapiens* dispersed from Africa into southern and southeast Eurasia, less than 150,000 years ago. In this view, both migration and replacement took place. A variation of this model is that another archaic *Homo* migrated into Asia before (*H. heidelbergensis*); *H. sapiens* is then the third *Homo* species to colonize Asia.

The issue is unsolved, although mitochondrial DNA and the fossil evidence support the replacement model. The large gap in the Chinese fossil record between the last occurrence of *Homo erectus* (ca. 400,000 years ago) and the first occurrence of archaic or posterectine modern humans (250,000 years ago) and a similar gap between the last occurrence of the archaic modern humans (120,000 years ago) and the first occurrence of true modern humans (not before 90,000 years ago) also support the migration and replacement model. On the other hand, the gap may be artificial, and future findings may fill it. In that case, a gradual change from *Homo erectus* through the intermediate posterectine premodern forms to *Homo sapiens* took place in Asia as well as in Africa. Regional continuity in anatomical features would support the multiregional model, but at present there is no firm evidence for such continuity.

The two models imply a totally different scenario for what happened to *Homo erectus* in Asia. If the first model—no migration, no replacement—is followed, the two *Homo* species cannot be found together, and if so *Homo sapiens* should be found in later archeological strata than *Homo erectus*. If the second model—migration, replacement—is followed, the two *Homo* species may be found together in the same stratum. *Homo sapiens* may have been the direct cause of extinction of *Homo erectus*, or perhaps this latter species was already extinct prior to the arrival of modern humans.

Reconstruction of "Java Man" (*Pithecanthropus erectus*, now known as *Homo erectus*) based on a skull cap, thigh bone and two back teeth discovered in Pliocene fossil beds in Trinil, Central Java, by Dr. Eugene Dubois in 1894. (Jupiterimages)

The archaic modern humans who replaced Asian *Homo erectus* bear different scientific names, according to the theory followed. The relict population in Indonesia is sometimes called *Homo soloensis*. Current alternative names for the Chinese fossils are *Homo heidelbergensis* and *Homo daliensis*. *Homo heidelbergensis* is supposed to be the Eurafrikan sister-taxon of *Homo erectus* and the precursor of Neanderthals. Originally, the species was limited in distribution to Europe. At present, based upon a skull from Africa (also known as *Homo rhodesiensis*), which is similar to a lower jaw from Heidelberg (Germany), the distribution is thought by some to be much larger, including China.

The end of *Homo erectus* on Java is better documented than its end in China. Java was colonized by *Homo erectus* already around 1.2 million years ago at low sea level stands. Gradually, the sea rose and the island became isolated again, resulting in a local evolution of *Homo*

erectus on the islands. Around 120,000 years ago a new sea level drop occurred, and a modern Asian rain forest fauna migrated into Java with orangutans and possibly *Homo sapiens*. The dramatic faunal turnover constituted the end of *Homo erectus* on Java.

The new arrivals on Java all indicate that the conditions at that time were wetter and warmer than before. Such a marked change in environmental conditions led to the extinction of many species of the earlier fauna, including *Homo erectus*. The newcomer, *Homo sapiens*, apparently was better adapted to living in a wetter and warmer climate than was *Homo erectus*.

The nearby island of Flores saw a similar colonization of modern humans, but here a relict population of *Homo erectus* seems to have survived the impact and managed to continue its local, endemic evolution toward dwarfism, eventually leading to a new species, *Homo floresiensis*. This dwarf human, nicknamed the “hobbit,” lived till 12,000 years ago. Stone tools made by *Homo erectus* found on Flores date to around 800,000 years ago, which means that the isolation was a long-term one, apparently sufficient to evolve into an insular dwarf.

The Ngandong (or Solo) fossils of Java are sometimes presented as a relict (surviving) population of *Homo erectus*. The date of the Ngandong fauna is, however, 200,000 years ago. This is confirmed by the character of the associated fauna, which consists of extinct elements such as dwarf stegodons. The younger dates such as 50,000 or even 27,000 years are based on elements from another period. A true relict population is seen only on Flores. These fossils indicate that *Homo sapiens* might indeed have had contact with latest *Homo erectus* in insular Asia between 100,000 and 12,000 years ago. Here, modern humans might have led to the extinction of erectine humans, either directly through hunting and extermination or indirectly through habitat destruction or diseases.

Into Europe and across Central and Northern Asia

When modern humans (*Homo sapiens*) left Africa, there is little doubt about much of their route into Europe: from a base in the Levant (eastern Mediterranean) and across Asia Minor into southeastern Europe. How they reached the Levant, however, is another question.

There are two competing theories for how humans left Africa. The most obvious is a northern route, from the Nile Delta eastward across the Sinai Peninsula into Asia. The other is a southern route, from the Horn of Africa and across the Red Sea to the Arabian Peninsula.

It is probable that modern humans used the northern route in an earlier failed migration out of Africa about 100,000 to 80,000 years ago. Evidence for this earlier migration comes from two caves, Skhul and Qafzeh, in what is now Israel. But those early *H. sapiens* migrants were displaced by a related species, *H. neanderthalensis*, that had replaced the modern humans by 70,000 years ago. There is no evidence that any modern humans are descendants of that earlier foray.

Both genetic data (especially patterns of genetic diversity) and dating of modern human archaeological sites suggest that migration that led to modern humans spreading across the globe followed the southern route out of Africa. Once on the Asian continent, the migrants could have followed the coasts of the Red Sea or the Persian Gulf through the interior of Arabia or even through what is now Iran to reach the Levant.

The great migration began between 75,000 and 60,000 years ago when the spread of northern ice sheets lowered sea levels and narrowed the expanse of water that migrant humans had to cross out of Africa. Initially, their movement north would have been blocked by desert conditions, but by about 50,000 years ago the climate moderated enough to permit movement northward. As they did so, they moved into areas populated by *H. neanderthalensis*. The Neanderthals held on for some time afterward before dying out about 24,000 years ago. Their presence may confuse some of the dating of putative modern human sites unless unequivocal modern human remains are present.

By the time modern humans arrived in Boker Tachtit in what is now Israel (47,000 to 46,000 years ago) and Ksar Akil in what is now Lebanon (45,000 to 43,000 years ago), they were to stay but not stay still. From their base in the Levant, they could move west into Europe, east into Asia, and even back into Africa by, ironically, the northern route.

By about 45,000 years ago modern humans had reached Asia Minor in Üçagizli Cave on the Mediterranean coast of what is now Turkey near Syria. From there, they could continue west, either along the Mediterranean and Aegean coasts or through the interior of what is now Turkey and cross the Bosphorus or Dardanelles straits into Europe. One putative modern human site, the Bacho Kiro Cave in eastern Bulgaria, dates to about 43,000 years ago.

The lower Danube River valley is key. Modern humans could follow it north of the Alps, obtaining ready access to central and northern Europe. They made quick progress, reaching what is now the Czech Republic shortly afterward and southern Germany by 38,000 years ago and crossing the Rhine Valley into what is now central France by 36,000 years ago. To the north, *H. sapiens* had moved into what is now western Ukraine by 35,000 years ago.

South of the Alps, modern humans likewise made rapid progress west. They reached sites in what are now northern Italy and northeastern Spain by about 40,000 years ago. Southern Italy was colonized from the north by 30,000 years ago. Southern Spain was colonized about the same time.

Ice blocked much of their access into northwestern Europe, including most of the British Isles. But to the northeast, in the Russian Arctic, much more land was available. Humans moving

northeastward had reached the Don River valley, in what is now Russia, by 42,000 years ago, and they had made it to the region of the northern Ural Mountains by about 28,000 years ago. As they spread across Siberia, they would have met migrants from the east, such as from what is now China.

As with Europe, modern humans could pass from the Levant into central Asia via either an eastern route through the mountains of what is now Iran and along the southern shore of the Caspian Sea, a central route through the Caucasus Mountains, or, once in Europe, a western route north of the Black Sea. It is possible that all three routes were used. From central Asia, they pushed through the mountainous spine of Asia to enter South Asia, primarily what are now Pakistan and India. Dating of a number of putative modern human sites suggests that they reached the Indian subcontinent by about 30,000 years ago.

■ Introduction: The First Americans

Who the first Americans were, when they arrived, and how they arrived are among the most contentious issues in world archaeology. The debate has escalated in

the last 20 years as new archaeological finds have brought conventional wisdom into question.

Until the late 1980s it was generally accepted that the first Americans were the Clovis people

who crossed from Asia to North America via a land bridge across the Bering Strait. These migrants were so-named because distinctive fluted stone spear points, as well as blades and cutting tools and fashioned mammoth bones, were discovered at Blackwater, near Clovis, New Mexico, in 1936–1937. Subsequently, numerous sites throughout North America, for example Murray Springs and Naco in Arizona, have yielded similar finds and reflect the food procurement strategies of these hunters who pursued animals such as the mammoth, horse, and bison, among others, and collected a wide range of plants. Most sites date to between 9500 and 9000 BCE and

have prompted the suggestion that the first migrants arrived approximately 13,000 to 11,000 years BCE before melting ice at the close of the last Ice Age caused the submergence of the Bering land bridge. They gradually moved south into Central and South America in search of big game. The Clovis culture prospered for circa 300 years, after which a range of disparate hunter-gatherer societies developed. Why this occurred remains unknown, though it may be associated with the extinction of many large animals (megafauna), which in turn may have been caused by altering environments and hunting pressures.

However, recent evidence from several North and South American sites has prompted a reappraisal of the colonization of the Americas. For example, several sites predate established Clovis sites. These include Monte Verde, southern Chile, where camp remains have been dated at 11,500 years BCE; the rock shelter at Pedra Furada, Brazil, where non-Clovis human remains and rock drawings date to circa 10,000 years BCE; and three sites in Patagonia dating between 9,000 and 8,500 years BCE. Several North American sites also yield pre-Clovis dates such as Big Eddy in Missouri, Page Ladson in Florida, the Schaefer and Hebior mammoth sites in Wisconsin, Walker in Minnesota, Meadowcroft Rock Shelter in Pennsylvania, and Cactus Hill in Virginia, where various artifacts date between circa 10,000 and 15,000 years BCE. Additional information includes DNA extracted from human coprolites (fossilized excrement) from Paisley Caves, Oregon, in 2008. First, the organic material is dated to 12,300 years BCE, which clearly predates Clovis and supports a pre-Clovis presence if only along an ice-free coastal corridor. Second, the DNA contained two sets of genetic sequences common to present-day indigenous Americans and native East Asians and Siberians, which reinforces the Bering land bridge as a chosen route.

Other suggestions include possible colonization from Europe by travel along the edge of the Northern Hemisphere ice sheet, independent colonization using boat transport from Southeast Asia, and migrants other than those from Siberia. Further evidence and dates will undoubtedly add to this debate.

Early Debates about the Peopling of the New World

Early theories concerning the peopling of the New World were largely grounded in myth or legend. It was not until Thomas Jefferson dem-

onstrated in 1784 that contemporary American Indian tribes were responsible for the large mounds found throughout the U.S. Southeast that theories became grounded in empirical evidence. Previously, many believed that these mounds had been the work of either the mythical Atlantians or one of the lost tribes of Israel. These speculations have been thoroughly discredited, but people continued to speculate about possible Old World cultures peopling the New World. For example, during the nineteenth and early twentieth centuries, some scholars theorized that Chinese junks had crossed the Pacific and reached the northwestern coast of North America and had peopled the New World. Others believed that Phoenicians from the Mediterranean made their way across the Atlantic or that West Africans reached eastern Mexico at some point during the late Holocene era.

Debates about the peopling of the New World changed in the early twentieth century when archaeologists discovered fluted spear points in diverse locations throughout the New World. These discoveries allowed them to argue for a single migration model to explain the appearance of the same technology across the New World at relatively the same time period. This model, which came to be known as the Clovis-First model, argued that the peopling of the New World took place no earlier than 11,500 years ago, based on the distinctive style of lithic point found in 1932 near Clovis, New Mexico. According to the Clovis-First model, a small group of hunters and gatherers, possibly numbering fewer than 100 individuals, entered the New World from Siberia at the end of the last Ice Age, approximately 11,500–12,000 years ago. Prior to that, it was believed that most of Canada was covered by the Cordilleran ice sheet that was centered over the Rocky Mountains and the Laurentide ice sheet centered over Hudson Bay, effectively blocking any way for peoples to enter the New World beyond Alaska. Clovis-First modelers hypothesized that at the end of the last Ice Age, a single migration of peoples funneled through an ice-free corridor that formed as a result of the melting of the two ice sheets.

The Clovis-First model was not universally accepted. In the work cited below, Alex Krieger argued that it was impossible to believe that the

THE CLOVIS SITE

The Clovis site, later named Blackwater Locality #1, is located approximately 7 miles (11 kilometers) north of the present-day city of Portales in eastern New Mexico. The site lies on the northern edge of Blackwater Draw and has produced the remains of 4 mammoths and 1 bison along with scattered remains of mammoth, bison, horse, camel, antelope, deer, wolf, peccary, turtle, rodents, and birds in addition to more than 166 lithic (stone) specimens. The site was first discovered in 1932 by E. B. Howard and John Cotter and spans a cultural sequence dating between 13,300 and 5,000 years before the present.

The archaeological evidence indicates that the site was originally a hunting and butchering site located near a watering hole, as lithic tools were recovered in direct association with extinct Pleistocene fauna. The association of lithic tools and Pleistocene fauna from this site was the first empirical proof that people were in the Americas by 12,500 years before the present, leading to the development of the Clovis-First hypothesis. This hypothesis argued that the first people migrated into the Americas at the end of the Pleistocene, bringing with them a simple lithic technology as discovered at the Clovis site. The lithic tools

recovered from the site were predominantly unifacial and were manufactured from blades and primary flakes. Only projectile points and bifacial knives, however, were flaked on both sides. Most of these primary flakes were made from Alibates flint from the Canadian River valley of the Texas Panhandle, indicating that the site was used on a seasonal basis by prehistoric hunters and gatherers. Evidence also indicates that these peoples dug wells to locate water and possibly to attract faunal resources. Although the Clovis-First hypothesis is no longer widely held, the Clovis site remains important in understanding early Native American lifeways.

New World was unoccupied before the appearance of fluted points primarily because there were numerous sites that seemed to predate Clovis-era points. These early sites, because they could not be conclusively dated to the pre-Clovis era, were often ignored by those who followed a Clovis-First model of entry. Linguists also entered the debates, siding either with those who favored a Clovis-First entry model or those who came to be known as early entry modelers and who argued for a pre-Clovis peopling of the New World. Many of these linguists analyzed American Indian languages and argued that American Indians had been in the New World for more than 12,000 years based on interlanguage separation and diversity, thus adding further controversy to the debates.

As a result, early debates concerning the peopling of the New World could be placed into two camps, either those favoring the early entry

model or those favoring the Clovis-First model. The early entry modelers argued that such sites as China Lake in eastern California, Pedra Furada in Brazil, and Meadowcroft rock shelter in Pennsylvania all demonstrate that people had been in the New World prior to the Clovis period. Clovis-First modelers argued that these sites were inconclusive and could not be accurately dated. Outside these two general schools of debate, a few scholars continued to argue during the twentieth century for alternative models concerning the peopling of the New World.

The Clovis-First model is no longer widely believed. Instead, scholars have returned to proposing variations of the early entry model. Although most theories still argue that the peopling stemmed from North Asia, alternative theories have become more prominent. Some of these newer theories stem from the early debates. For example, some have argued that prehistoric Euro-

peans, and not North Asians, populated the New World. In 1941 Frank Hibben reported finding leaf-shaped bifaces and the remains of extinct fauna in the deepest culture-bearing stratum of Sandia Cave. Hibben noted that the flaking technology of the Sandia artifacts more closely resembled the Solutrean technology of Paleolithic era France than Clovis-era fluted points.

The North Asian Origins of the First Americans

It is generally recognized that the original New World populations migrated from North Asia. North Asia consists of all of present-day eastern Russia and northern Mongolia, including Siberia and surrounding areas. Although North Asia was inhabited by the middle Pleistocene era (ca. 500,000 years ago) or earlier, population levels did not expand throughout the area until the late Pleistocene era. Yet these peoples did not move into the Americas until they faced expanding population pressure and environmental changes. The evidence for the North Asian origins of the first Americans, although inconclusive, argues that these people migrated into the Americas largely from around the Lena and Kolyma river basins, located in present-day northeastern Siberia, beginning in the late Pleistocene era (ca. 35,000–15,000 years ago).

With the exception of the Diring Yuriakh site no credible evidence of human presence

earlier than the late Pleistocene era has been discovered in North Asia. The evidence of human settlement found at the Diring Yurakh site is contested. The oldest accepted sites in North Asia are known from the middle and lower Aldan River of Sakha (Ust-Mil 2 and the Ikhine sites), which date to circa 35,000 years ago. However, by this time archaeological evidence indicates that there was a unity among eastern and western Siberian sites in their virtually universal possessions of characteristic late Pleistocene artifact assemblages. The only exception to this general pattern is the Layer VII assemblage from the Ushki locality in Kamchatka, where the stemmed bifaces of the lowest component are at variance with this general lithic characteristic. This general lithic pattern argues, however, that the first Americans came from North Asia because of the close resemblance and chronology found between Alaskan and Yukon assemblages and North Asian assemblages.

The largest group of sites in North Asia thought to be tied to the first Americans lies in the Lena River basin. This area contains a massive river system that drains the Central Siberian Plateau and higher upland areas and mountains to the south and east. With the exception of Dyuktai Cave on the Aldan River, these sites all represent open-air occupations located on low or medium river terraces near stream confluences. Localities on the Aldan River include Ust-Mil 2, Ikhine 1–2, Verkhne-Troitskaya, Ust-Timpton 1, Ezhantsy, and Tumulur. Several important sites from this period are also located along the Olekma River, including Kurung 2 and Leten Novyy 1.

Evidence further indicates that these first Americans of North Asian origin likely moved into the Lena Basin from the Middle Amur River, and the southern Primorye. Sites located in the Middle Amur area are found in the Zeya-Bureya Lowland, and include one possible early locality along the Zeya River (Filimoshki) and several sites along the Amur River (Kumara 1–3). Sites in the southern Primorye occur on both sides of the Sikhote-Alin Mountains, which extend along the coast of the Sea of Japan. They include Geographical Society Cave on the Suchan River and several open-air localities situated along small rivers, most notably Osinovka and Gorbatka 3 on

➤ DID EUROPEANS MIGRATE TO THE NEW WORLD?

Whether prehistoric Europeans possibly migrated to the Americas prior to Columbus's discovery has been a question of interest for more than 200 years. By 1891, Rasmus B. Anderson published *America Not Discovered by Columbus*, which contained a bibliography of 350 sources on the topic. It listed claims of America's discovery by the Chinese, Arabs, Welsh, Venetians, Portuguese, and Poles. However, the majority of the references supported the notion of Vikings as the first to arrive in the Americas.

This hypothesis was confirmed in 1960 when Helge Ingstad discovered Norse ruins at L'Anse aux Meadows on the northern tip of Newfoundland. More recently, several sites and lines of evidence have been cited as supporting an even earlier migration of Europeans into the New World. This hypothesis, called the Solutrean hypothesis, postulates that Upper Paleolithic peoples from Europe, utilizing Solutrean lithic technology, migrated into the Americas during the late Pleisto-

cene era. Evidence supporting such an argument remains elusive and highly controversial primarily because the Solutrean ended in Europe at least 5,000 years before the Clovis technology appeared in the America. Furthermore, there are major differences between these two technologies in terms of lithic composition.

the Illistaya River, and Ustinovka 1 and Suvorovo 3 on the Zerkalnaya River.

Some have used the above evidence, along with morphological data, to argue that some of the first Americans may have originated from along the Japanese littoral. However, the genetic evidence supports the theory of the North Asian origins of the first Americans, although it traces their origins further back in time (ca. 35,000–25,000 years ago) based on Y chromosome and mitochondrial DNA (mtDNA). The major Y haplotype present in most American Indians has been traced back to recent ancestors common with Siberians. These ancestors include the Kets and Altaians from the Yenisey River Basin and Altai Mountains. The next common ancestor gave rise also to Caucasoid Y chromosomes, probably from the central Eurasian region. The mtDNA evidence argues for a similar conclusion, although it places the homeland of these first Americans somewhere between contemporary Mongolia and Siberia, most likely around present-day Tibet and Ulan Bator. This is based on evidence indicating that all mtDNA lineages

can be found in Siberia except lineage B, which is found in the Ulan Bator region of North Asia.

The linguistic evidence also argues that the first Americans came from North Asia. This is based on phylogenetic language comparisons which indicate that American Indian languages are more closely linked to North Asian languages than any other known languages in the world. Linguistic analysis, however, is unable to give any finer resolution to the debate over where in North Asia the first Americans originally came from. Some attempts have been made to link linguistic, genetic, and dental evidence together, placing the North Asian origins of the first Americans in southern Siberia and surrounding regions, but all attempts have been met with a high level of skepticism based on a lack of empirical evidence.

Into South America

Current evidence indicates that by the end of the Pleistocene era (approximately 12,500 years before the present), humans had already occupied the major environmental zones in South America. These peoples enjoyed diverse cultural traditions and different levels of technological development and subsistence patterns. It is unknown how and exactly when these peoples moved into these areas, but recent scholarship has argued that the dates were earlier than has been traditionally believed.

Early studies attempting to reconstruct specific colonization routes and times relied largely on geographic data that looked at South America on a continental scale. For example, Carl Sauer explicitly ruled out movement along the Pacific Rim of South America because of this region's difficult topography. He argued that the first South Americans colonized the eastern portion of the continent. This geographically based entry model was founded upon a supposed relationship between Clovis-type points associated with North America and a scatter of stemmed fishtail points found from Central America and throughout the Andean chain to the tip of South America. Since scholars often associated Clovis-type points with big game hunting lifestyles, they assumed that the makers of fishtail-type points were descendants of big-game hunters who had migrated from North America. Recent studies, however, have demonstrated that any relationship with Clovis technology and the lithic points found in South America is tenuous since very few South American fishtail points are fluted, and those that are were not crafted using the same methods as with Clovis. Furthermore, most paleobotanical evidence indicates that the first South Americans, like their North American counterparts, practiced a diverse hunting and gathering lifestyle. Thus, they would not have been restricted to following large animals in the grasslands and savannas of eastern South America.

Current evidence suggests that the first South Americans did not follow the coastline for

WHAT WAS FOUND AT MONTE VERDE?

Monte Verde is credited as the earliest human occupation site in the New World. The site, in south-central Chile, is located by a small creek near the Pacific Ocean. It is believed to have been occupied about 12,500 years before the present. This site predates various Clovis sites, originally believed to have been the earliest human occupations sites in the New World, by about 1,000 years.

The Monte Verde site, first excavated in the late 1970s by archaeologist Tom Dillehay, was heavily analyzed and scrutinized by the archaeological community for at least 20 years. Based on materials collected, scientists have surmised that the site was occupied by a hunter-gatherer group. Optimal conditions at the site allowed for the preservation of various organic materials such as animal hides, wooden stakes, and bones. These organic materials as well as the stone tools found at Monte Verde helped support the claim that the site was occupied by humans, since the materials showed evidence that they were worked and manipulated by humans. Artifacts also indicate the presence of huts, fire places, and tent stakes with knotted ropes attached. Scientists believe that the people who inhabited Monte Verde gathered local flora such as berries, chestnuts, potatoes, and mushrooms and also hunted wild game, as evidenced by mastodon bones found at the site. Archaeological evidence shows that the Monte Verde people also fished but relied more on hunting and gathering. They lived in tentlike structures that were covered by animal hides.

—Christine Boston

long. They either continued down along the western side of the Andes or proceeded along the Caribbean and Atlantic coasts and into the central part of the continent to the east of the Andean chain. Movement throughout the interior of South America during the late Pleistocene was not as difficult as today primarily because much of the interior was covered with grassland, scrub forest, or savannas. Tropical rain forest environments were only present in the western Amazon basin, where movement and settlement may have been difficult. Despite these two routes of colonization, archaeological evidence indicates that people had colonized

most of South America by the end of the Pleistocene era, although population densities did not reach high levels until the Middle Holocene era.

The site of Taima-taima, located in the Caribbean coastal zone of Venezuela, has revealed a fragment of an El Jobo point in the pelvic cavity of a mastodon. The bones bore clear-cut marks indicating Late Pleistocene human activity. Likewise, the site of Tibitó, located in a small basin on the Sabana de Bogotá high in the Andean uplands of Colombia, has revealed clusters of bone fragments and stone artifacts. This site has been dated to the end of the Late Pleistocene era and reveals that prehistoric Andean peoples were living in the Andean uplands by this time.

Archaeologists have discovered several sites along the Pacific Coast route and found evidence from the desert Pacific coast of southern Peru that indicates that populations developed a specialized maritime economy beginning in the Pleistocene era and continuing through the Early Holocene era. For example, the site of Quebrada Jaguay indicates that peoples were intensively exploiting fish, marine clams, crustaceans, and seabirds by the end of the Pleistocene era. The site of Monte Verde, 1,553 miles (2,500 kilometers) farther south, suggests that Late Pleistocene peoples successfully utilized the varied resources of woodland and wetland environments that existed in the temperate rain forests of south-central Chile at the time.

In the interior uplands of eastern Brazil, where more than half a dozen archaeological sites have been dated to circa 9000 BCE, evidence indicates that the first South Americans were not as specialized as peoples on the Pacific

coast. Lapa do Boquete, for example, is a large limestone rockshelter that suggests that prehistoric peoples hunted and gathered palm nuts, freshwater mussels, fish, and small- to medium-sized mammals.

Early foragers also successfully adapted to the tropical rain forest of the Amazon basin by the Late Pleistocene era. The lowest occupation level at Caverna da Pedra Pintada, a large rockshelter in a sandstone bluff just north of the Amazon River, has been dated to circa 9000 BCE. Floral and faunal remains indicate a broad-spectrum foraging economy that used a small but varied lithic assemblage as well as bifacial stemmed points and thick unifacial scrapers.

■ Introduction: Miscellaneous Movements

Aside from the major movements of *Homo sapiens* that populated our planet, there have been innumerable migrations of humans in our prehistory. Many of these movements can be traced in multiple ways, including artifacts, remains of plants and animals, human remains, and, increasingly, both modern and an-

cient DNA. Large-scale movements are relatively easy to identify, but there are likely to have been many "local" movements that will remain invisible to the archaeologist and historian.

In the absence of human remains and DNA, archaeologists and historians have debated how artifacts originate in one region and are then

found in a later time period in another. Do ideas—that is, concepts of artifact form, subsistence practice, and social relationships—diffuse from one population to another, or are they moved by people who physically carry them into these new locations? This debate, then, pits diffusion against migration as competing explanations of the appearance of artifacts and other cultural traits in regions across the globe.

For much of the past, it is likely that both diffusion and migration had roles to play in the spread of cultural materials. People are excellent borrowers and imitators and will borrow ideas and concepts when they can be usefully adapted into local circumstances. For example, for most of the early twentieth century, archaeologists believed that the idea of plant and animal domestication diffused from a Near Eastern heartland into Europe and beyond. Although there may well have been local instances where this may have been true, the evidence is overwhelming that people migrated from the Near East and carried their plants and animals with them. The analysis of ancient and modern DNA shows clear traces of these ancient migrants in contemporary European populations.

The causes of migrations are hotly debated within archaeology. Environmental change has long been seen as a likely cause for movement; long-term, persistent, and severe drought is known to have forced people to move from dry regions to more fertile ones. Cultures are resilient, however, and instead of moving, they may develop new subsistence strategies and cultural practices that allow them to stay in their familiar places. Another cause of migration is population growth. As a local population begins to grow, it may soon begin to outstrip the capacity of a subsistence system to feed the growing population. An alternative to changing subsistence practice—that is, to intensify resource production—may be to simply move to an uninhabited place. Population pressure of this kind has been identified as one of the likely causes of the movement of peoples out of the Near East at the advent of the Neolithic. During the Paleolithic, populations that experienced resource shortfalls probably moved frequently since they had relatively few neighbors. As populations grew denser, however, with the advent of villages and seden-

tary groups, movement became a less common response to increasing resource shortfalls.

Other causes for population movement include warfare and the inability of existing social institutions to prevent political frictions within groups. However, these causes would have been relatively uncommon for most of our evolution and would only have become more prominent after peoples began to become more sedentary.

Some population movements have involved the invention of new technologies. To move domesticated animals and plants into the Aegean Islands, for example, more sophisticated watercraft were required. And movement into very cold or very high-elevation environments required the development of warm clothing. Extreme environments like the Arctic or the Tibetan plateau were occupied relatively late in our prehistory only after our species was capable of inventing these technologies.

The Spread of Agriculture into Europe—Diffusing Ideas or Moving Peoples

The beginnings of agriculture are to be found in the Near East from where the knowledge of plant cultivation spread into neighboring areas of Anatolia in what is modern-day Turkey. There is evidence for sedentary communities in Anatolia practicing horticulture on a small scale from the ninth millennium BCE onward. The first settlement with an agrarian population that continued to flourish for a longer span of time (more than 1,000 years) was Çatalhöyük in the Konya Plain (southern Anatolia).

The cultivation of plants for food production and the raising of cattle require the mastering of a set of specialized technologies. The knowledge of these technologies and their application is called the Neolithic package (or agrarian package). There is a consensus among

➤ MARITIME MOVEMENTS INTO THE AEGEAN, 7000 BCE

Trade routes linking Anatolia with the Aegean area and continental Europe can be assumed to be very old, dating at least to the eighth millennium BCE. Indicators of early trade relations between people settling on both sides of the Aegean Sea and beyond are trade goods such as obsidian (from the island of Melos and traded to mainland Greece) and spondylus shells, which found their way from the coasts of the Aegean inlands. Trading contacts were facilitated by the land bridge that linked Europe with Asia until circa 6700 BCE, when the Bosphorus Strait opened.

Later, such contacts continued under the auspices of a network of maritime routes that were frequented by people from Anatolia and southeastern Europe moving in both directions. Maritime movements in the early millennia BCE have to be imagined as short-distance travels between the islands. At certain times, the Dardanelles and the Bosphorus connected people settling on either side; in other periods, they functioned as geographical and even cultural divides. For instance, during the fifth millennium BCE there was much movement in the convergence zone around the Aegean, while during the fourth millennium BCE the Dardanelles functioned more like a dividing line. Contacts became lively again toward the end of that era. The Ezero culture in Bulgaria is known to have inspired pottery styles and ornamentation of Troy I. Troy, at the southern tip of the Dardanelles, was founded around 2950 BCE.

—Harald Haarmann

scholars that agriculture spread from western Asia and reached southeastern Europe from Anatolia sometime before 7000 BCE. What has remained a matter of scientific debate to the present is the way in which the agrarian package was adopted by the ancient populations that settled around the Aegean Sea.

There are two hypotheses of the spread of agriculture into Europe that, at first sight, seem to exclude one another but that from the perspective of the history of human ecology both have a weight in explaining how early agrarian settlements emerged and developed in Europe. The two hypotheses emphasize different scenar-

ios for the spread of the agrarian package into Europe.

The first stresses migration as the source of spread (the agrarian package spread with the movements of ancient populations leaving Anatolia and migrating into Europe). In a modern version of the migration hypothesis, the spread of agriculture is linked to the assumed movements of Indo-Europeans from western Asia. However, the most ancient elements of agricultural terminology in the languages of the Balkanic region are of pre-Indo-European fabric.

The second theory considers idea diffusion as the source of spread (the knowledge of agriculture spread to local populations in southeastern Europe that acculturated and adopted a sedentary lifeway). The old indigenous population left its genetic footprint in the region (see below).

The earliest evidence for the practice of agriculture in the Aegean comes from Crete (the area of Knossos), dating to circa 7000 BCE. The dates for the beginnings of agriculture in continental Europe (the plain of Thessaly in Greece, coastal areas of the Black Sea in Bulgaria and Rumania) are somewhat earlier. The archeological record in southeastern Europe does not show evidence of large-scale immigration during the eighth or seventh millennia BCE. This means that the earliest agrarian communities were local people who had experienced the transition from a hunter-gatherer economy to the sedentary lifestyles of agriculturalists through acculturation. Those people had previously established trade contacts with the agriculturalists in western Anatolia, from whom they adopted the knowledge and the technologies of plant cultivation. Judging from the traces of a small-scale immigration in the seventh millennium BCE, this was directed and remained limited to the plain of Thessaly in eastern Greece.

There is ample genetic and linguistic evidence to show that the hunter-gatherers who inhabited southeastern Europe prior to the advent of the Indo-Europeans were of non-Indo-European stock. On the genetic map, the footprint of this ancient population is recognizable as a divergent genomic profile, called the Mediterranean outlier by geneticists. This profile is distinct from the genetic composition of all surrounding populations.

According to the migration hypothesis, the hunter-gatherers were driven out of the arable land, where the immigrating agriculturalists then settled and built their communities. And yet there are weighty arguments that stand against this assumption, and these come from the most vivid documentation of human activity, language. A broad layer of loanwords can be identified that survived, as relics from the language of the indigenous people, in ancient Greek and in languages of the Balkans. These also include agricultural terms and vocabulary of other technologies that developed in the agrarian communities such as weaving, pottery, and house construction.

These pre-Greek elements that are attested in the lexicon of ancient Greek support the assumption that the hunter-gatherers of Old Europe were not displaced by immigrants but that they adopted the agrarian package via idea diffusion and adjusted to agrarian lifestyles. Otherwise, they would not have developed a terminology for the agrarian package in their native language. The early indigenous agriculturalists crafted a cultural sphere where settlements were linked by intense trade relations for mutual advantage. This cultural complex with its egalitarian society has become known as Old Europe.

The spread of agriculture from southeastern Europe into the central part and the east of the continent unfolded in several waves. By circa 5500 BCE the agrarian package had reached southern Russia and by circa 5000 BCE had reached the British Isles. The spread of agriculture into central Europe was swift and is linked to the LBK (Linearbandkeramik) culture, named after their particular ornamentation of pottery in linear bands. The absolute time of the speed of spread was estimated according to a wave of advance model. This model, however, is too theoretical and cannot explain the various local conditions of human ecology. The archaeological insights from agrarian communities illustrate that older settlements expanded and that in the course of time plant cultivation shifted from the most fertile to less fertile arable land in the surroundings. Thus, the spread of agriculture in Europe unfolded under specific local conditions of land exploitation and the exploration of new terrain for settlements.

Later, during the sixth millennium BCE, there is genetic evidence for a populous migration movement from western Asia into Europe. This movement might have been caused by the climatic change around 5800 BCE, a rapid warming that resulted in a drying out of much of the arable soil in western Anatolia and might have forced the inhabitants to move. For instance, Hacilar was abandoned around 5500 BCE. The movement from western Anatolia in the sixth millennium BCE, however, is not related to the early spread of the agrarian package because agriculture had already spread earlier throughout most parts of the continent.

How Many American Migrations?

Current archaeological evidence indicates that the first Americans migrated from northern Asia into the Americas sometime during the late Pleistocene era (130,000–12,500 years before the present). How many migrations took place and by which routes, however, are still unresolved by scholars. The historic Clovis-First model argued that a single migration took place around 12,500 years before the present and that this migration funneled south through an ice-free corridor located along the eastern flanks of the Rocky Mountains, eventually populating all of the Americas. More recent models, based on archaeological, geographical, genetic, morphological (characteristics defining the form and structure of an organism), and linguistic data refute the simplistic, linear Clovis-First model and instead argue for multiple

► HUMAN ADAPTATION TO LIVING CONDITIONS IN HIGH ALTITUDES—CHUSANG ON THE TIBETAN PLATEAU

Findings from recent geological and archeological research emphasize the importance of prehistoric sites on the Tibetan plateau that provide evidence for the early presence of humans in the region. In the mid-1990s remnants of a hearth and human footprints in a sedimentary deposit were found at Chusang, west of Lhasa. The footprints originated when human beings (adults and children) stepped onto mud that hardened under the influence of carbonate in a later overlay of water from a hot spring. Optically stimulated luminescence dating produced a high age for these remains. If the date given of circa 21,000 years before the present can be confirmed by other dating methods, then Chusang is the oldest campsite in Tibet. More recent dating, however, places the age of the site at approximately 30,000 years ago.

The presumed high age makes the site sensational in its significance for the history of human evolution. The Tibetan plateau was inhabited already at the time of maximum glaciation during the last Ice Age, and the region was not covered by a thick layer of ice. Living conditions in the area at an elevation of 13,779 feet (4,200 meters) must have been extremely harsh. Prehistoric Chusang provides evidence for early human adaptation to life in high altitudes. So far, no artifacts (i.e., tools or mobile art) have been found at the site, which still awaits systematic exploration.

migrations accomplished in different ways. These more recent models argue that several migrations into the Americas took place during the Late Pleistocene and Early Holocene eras along several different routes and that these migrations did not follow a single north-south migratory pathway.

Archaeological evidence indicates that the earliest Americans made several types of lithic

points (stone arrowheads), ranging from fluted points such as Clovis and Folsom points in North America to fishtail-type points in South America. This evidence was originally taken to be indicative of a single migration wave whereby fishtail points were thought to be a type of Clovis point used by the first South American migrants from North America. Presently, however, it is generally accepted by archaeologists that the first Americans created different point styles in different regions and that little migratory evidence can be discerned based on point dispersals alone. For example, although several Clovis points have been recovered from sites dating between 11,200 and 10,900 years before the present on the Great Plains, Clovis points are actually more common in the Eastern Woodlands, where they have been dated somewhat earlier at several sites. Furthermore, Clovis-like fluted points are rarely found in Central America as far as Panama, and only a few Clovis-like points have been reported from Colombia and Chile. Stemmed fishtail points, on the other hand, are more common in South America, and several sites in the southern cone have yielded fishtail points dated to as early as 11,000 years before the present. If a single migration took place, as suggested by the Clovis-First model, then such a model would require that a viable breeding population had migrated about 7,456 miles (12,000 kilometers) from northern North America to southern South America within a few hundred years to fit with the archaeological data. As suggested by archaeologists Alan L. Bryan and Ruth Gruhn, however, a more parsimonious model argues that during the Late Pleistocene era several waves of first Americans brought a relatively simple retouched flake industry with them from northeast Asia that they subsequently modified based on their particular needs, a model that could account for the relative simultaneous appearance of fluted and stemmed points throughout North and South America.

Furthermore, because there is no clear spatial or chronological gradient in initial archaeological dates of first American sites, single-wave models suggest that any expansion of peoples into the Americas was both spatially and chronologically rapid. As such, individuals would have needed to migrate 3.7 to 6.2 miles (6 to 10 kilo-

meters) per year between birth location and adult residence to account for the archaeological evidence, an unlikely proposition based on ethnographic data from contemporary hunter-gatherer migration rates. More recent evidence indicates, on the contrary, that numbers of sites or of discarded artifacts (such as lithic scatters containing fluted projectile points of early migrants) are more parsimoniously understood as markers of cumulative occupancy rather than indicators of individual migrating groups. Such an interpretation is more in line with models arguing for several migration waves because such an interpretation does not require such a rapid initial peopling of the continents.

Although geographic data is unable to provide evidence on the exact number of migrations into the Americas, it is able to indicate whether there was more than one migration wave. Geographically, there were two primary paths into the Americas once across the Bering land bridge, either along the eastern flanks of the Rocky Mountains and through an ice-free corridor or along the northwestern coast along modern-day Alaska by means of coastal refugia (an area that has escaped detrimental changes to a habitat) that remained unglaciated. Archaeological evidence spanning the Late Pleistocene and Early Holocene transition period demonstrates that both geographic routes were in use during the initial peopling, indicating that different migratory groups used different pathways to enter the Americas.

Corroborating the archaeological and geographical evidence, molecular genetic studies of North Asian and Native American populations indicate that several migrations took place, although at an earlier time than the archaeological evidence can empirically confirm. The molecular genetic data indicates that the initial migration into the Americas originated in south-central Siberia between 35,000 and 20,000 years before the present. Early migrants are hypothesized to have followed the northwestern coastal route until they were south of the American glacial ice sheets. As they migrated throughout the continent, they brought with them similar genetic makeup, as has been deciphered by archaeologists studying the mitochondrial DNA of their remains. Furthermore, different genetic makeup of

a second group suggests a later second migration. A third migration is hypothesized to have taken place after the Last Glacial Maximum period in northern North America, giving rise to present-day Aleuts, Eskimos, and Na-Dene peoples.

One of the postulates put forth by single-wave models is that indigenous American populations should constitute a homogeneous population. The molecular genetic evidence does not support such a postulate but rather supports the conclusion that several migrations into the Americas took place, primarily because indigenous American populations are genetically heterogeneous. A similar conclusion is also supported by the cranial morphological evidence. For example, studies comparing Early Holocene cranial morphological characteristics with worldwide human cranial variation have found that the first Americans were morphologically diverse. However, the cranial morphological evidence has once again also brought into question whether all migration waves originated in North Asia. Originally suggested by archeologist Frank C. Hibben with his discovery in 1941 of bifaces (two-sided stone tools) that resembled Upper Paleolithic Solutrean points, more recent cranial morphological and archaeological evidence has been used to argue for a possible migration from prehistoric Europe, or possibly Oceania, into the Americas. For example, at the site of Santana do Riacho, dating between 9,500 and 8,200 years before the present and located at Lagoa Santa/Serra do Cipó in the state of Minas Gerais, Brazil, cranial morphology of skeletons is characterized by long and narrow neurocrania (skull around the brain) and low and narrow faces with low nasal apertures and orbits. These crania exhibit stronger morphological affinities with present-day Australians and Africans than any other world population, and they show no resemblance to recent northern Asians. As such, these findings have led some researchers to conclude that more than one migration took place and possibly from more than one continental region. Likewise, the Cactus Hill site in Virginia, for example, presents evidence of a pre-Clovis occupation with lithic tool characteristics that some have attributed to be of Solutrean technology. However, the molecular genetic and linguistic data does not support the

hypothesis that prehistoric Europeans or peoples from other continents migrated to the Americas during the Late Pleistocene or Early Holocene eras, complicating the picture.

The final line of evidence supporting multiple migration waves is linguistic. The hypothesis put forth by Greenberg that all indigenous American languages can be reduced into either Amerind, Na-Dene, or Eskimo-Aleut language stocks is highly controversial and largely rejected. Instead, the diversity of prehistorically found indigenous languages is not thought to be reducible beyond several dozen language stocks. If a single-wave model is to fit with the linguistic data, then the initial migrating population would have had to have spoken more than one language. As with the other types of data, a more parsimonious interpretation is that several migrations into the Americas took place, one possibly for each language stock.

Moving into the World's Extreme Environments

Modern humans are the only species that have spread throughout the world, leaving out only the most inaccessible and uninhabitable regions

such as the polar zone, the most arid deserts, and the highest mountain ranges. And yet even in Antarctica there are some permanently inhabited settlements, and even the waterless routes through the western Sahara are frequented by Berbers (Touareg).

There are at least two other hominid species known to have peopled wide areas of the Old World, and these are archaic humans and *Homo erectus*. The latter species left Africa, the homeland of all hominid species, and spread throughout vast areas of Eurasia. Archaic humans in their European subspecies, the Neanderthals, in particular reached out farther than *Homo erectus*. But it was modern humans who explored all habitable lands on all continents.

According to the general idea of adaptation as propagated by evolutionary theory, the drive of hominids to explore the regions of the world cannot be explained. There was no need for adaptation that would have brought humans to extreme environments because they could have stayed in regions with more prosperous living conditions. And yet there is a driving force, innate in modern humans, that the other hominid species lacked or only possessed in a rudimentary form, and this is intentionality. This driving force that exceeds the goals for physical survival is the source for the individual's curiosity, for the testing of one's capabilities, for the discovery of the unknown, and for the mobilization of one's inventiveness. Intentionality induces complex behavior such as exploration, and this is an expression of a higher-order consciousness, typical of modern humans and untypical of previous hominids.

Humans in early prehistory might have moved into extreme environments as a result of the challenge to explore the unknown, not because they would have been forced by ecological constraints to do so. In later periods of the history of human settlement, many people were displaced and forced to live in extreme environments because of outside pressure. Numerous cases of displacement are known, such as that of the Amerindians who were pushed into areas that were not suitable for agriculture or herding by the white settlers or that of the Australian Aborigines who were driven into the deserts of the Australian inland under the pressure of colonizing European immigrants. There is no ground to

► LIFE IN PREHISTORIC SIBERIA

Modern humans reached Siberia from the west between circa 40,000 and 35,000 BP. They moved south of the ice sheet that covered the northern part of Siberia during that time. In the area around Lake Baykal in central Siberia, a number of sites have been discovered that belong to a zone of Paleolithic culture. The oldest of them is Tolbaga, east of the lake, where human presence is attested at circa 35,000 BP. The best known of the Siberian sites and the one with the richest variety of tools and other artifacts is Malta.

The Siberian Malta—not to be confused with Malta in the Mediterranean—is situated west of Lake Baykal in central Siberia, in the valley of the river Belaya, about 15.5 miles (25 kilometers) from its confluent with the Angara and at a distance of about 50 miles (80 kilometers) from Irkutsk. The site was discovered by M. M. Gerasimov in 1928 and excavated until 1958. The cultural strata of a Paleolithic settlement is found at a depth of 3 feet (1 meter) below the modern surface. Several encampments, the grave of an infant, and abundant remains of human activities have been unearthed at this site.

The settlement dates to the last Ice Age and human presence in the area extends for several millennia from circa 23,000 BP onward. On the basis of analyses of pollen and of the bones of animals, it can be established that the people of Malta lived under the harsh conditions of the polar tundra, which was roamed by mammoth, bison, reindeer, and other animals. The vegetation was

comprised mostly of herbs. Tree species such as pine and birch that could stand the cold were rare.

The minds of the prehistoric inhabitants of Malta were not only set to physical survival as one might expect, judging from the extreme living conditions. In addition to a vast array of stone tools, many pieces of Paleolithic mobiliary art were found at the site, among them dozens of female figurines, small sculptures of animals (bears and water fowl in particular), pieces of adornment such as bracelets and diadems, and a plaque with incisions on both sides. These artifacts were all made of mammoth bone and ivory.

Separated from this zone of Paleolithic culture around Lake Baykal is an isolated site in the middle valley of the river Berelekh, a tributary of the Indiguirka. This prehistoric encampment is the northernmost in the world of the sites with human presence in the Paleolithic age, at 71° northern latitude. The site was discovered in 1970. At a depth of 7.5 feet (2.5 meters) below the modern surface, bones of various animal species (among them mammoth, bison, horse, reindeer, polar fox) and several types of stone tools were found. The encampment was occupied between circa 13,400 and 12,900 BP.

assume such kind of motivation for population movements in early prehistory except for claims that modern humans drove the Neanderthals into remote areas where they encountered them in western Europe.

The impact of ecological factors is likely to keep humans away from extreme environments. In certain regions of the world, one can observe the abandonment of previously settled areas because of ecologically changing conditions. This is true for the Sahara, which was once covered by wide fertile savannas and was rich in rivers and lakes. Well into the fourth millennium BCE northern Africa received rain with the monsoon winds, which later changed direction. As a re-

sult, the Sahara gradually dried out in a long process that is still occurring today. In search of water and grassland for their cattle, the inhabitants of the formerly fertile areas traveled farther south. This movement brought more and more people to the Sahel zone, bordering the Sahara in the south. Eventually northern Africa became depopulated except for the coastal strip of the Mediterranean and the Atlantic and the oases in the desert.

Modern humans explored the cold rim of the Northern Hemisphere relatively early, between approximately 45,000 and 40,000 BP, migrating from the Near East farther north, around the Caspian Sea and/or crossing the plains of

central Asia. Their movement came to a halt near the edge of the massive ice sheet that had covered northern Eurasia during the last Ice Age. There were only two geographical directions that opened to continued movements: one to the west and into Europe, the other to the east and into southern Siberia. Both options were chosen and there is archaeological evidence for the presence of humans in Europe and in Siberia that dates back more than 35,000 BP.

Those early inhabitants of Eurasia were archaic hunters who had not yet invented the most effective hunting weapon of prehistory, the bow and arrow. Judging from the remains of bones at campsites, the mammoth and the reindeer were the most preferred animals for their diet. After the ice shield had melted, living conditions in Europe changed dramatically, while in Siberia climatic conditions of the Ice Age continued in the north.

The archaic hunters could have stayed in the southern zone. Instead, they moved farther north into the areas that had been freed by the ice and beyond and continued to live in the circum-polar zone. Their form of subsistence, hunting and gathering, did not change, although there was a transition from big game to small game hunting. In later periods the economy expanded to include reindeer herding. The sustainability of the communities of the peoples of northern Siberia has depended for millennia on hunting, fishing, and herding as the only forms of subsistence that can be practiced in the polar tundra and in the forest zone of the taiga.

Human ecology is determined by three major resources of life that function as arbitrators of living conditions in general and of extreme conditions in particular, and these are temperature, precipitation (amount of rainfall), and the composition of the air. What makes certain regions of the world uninhabitable is the deficiency or the lack of one or several of these factors. Extreme ecological conditions may be found in the following zones:

- The Arctic zone (i.e., the circum-polar zone of permanent and/or extreme cold climate, with average annual temperatures below the freezing-point). Habitation in the Arctic

zone expands from the area of the Saamic settlement in northern Scandinavia over northern Eurasia, Alaska, and the Canadian North to the settlements in Greenland.

- The arid deserts (i.e., zones with extremely high temperatures and extremely little precipitation). Such zones are found in Africa (Sahara, Kalahari, etc.), Asia (Saudi Arabia, central Asia, Gobi, etc.), the Americas (southwestern United States, Atacama in northern Chile, etc.), and Australia (outback). The Arab nomads of the Arabian Peninsula in historical times, the Touareg in the western Sahara and the San in the Kalahari up to the present, the Mapuche in northern Chile, the Aborigines in central and western Australia, and the Hopis, Navahos, and Apaches in the North American Southwest adjusted to extreme arid conditions.
- Extremely elevated zones (i.e., in the highlands of Tibet, in the Himalayas, in the Andes of South America). In Tibet the highest permanent settlements are at a level of 15,000 feet (5,000 meters), the highest in the world. At an altitude of about 6,000 feet (2,000 meters), the air becomes thinner, and in order to guarantee a regular supply of oxygen, breathing becomes heavier. Such conditions put humans and animals under stress. For instance, horses are not adept at carrying heavy loads in the high Andes, a task that is given to llamas, which are adapted to thin air.

Extreme ecological conditions may also be characterized by an overabundance of heat and rainfall. This is true for the zones with rain forest (central Africa, Amazon region, Southeast Asia, etc.). Human beings such as the pygmies, Amazon Indians, negritos in Malaysia, and others have also adapted to the living conditions in the jungle.

Politics and Statecraft

Because this era covers almost five million years of human evolution, it is difficult to define suitably the concept of politics. At its start, it is likely that our ancestors were living in social groups similar to those we see among our modern primate relatives, such as the chimpanzee. Here, politics is based upon parallel dominance hierarchies for males and females, and ultimate authority is exercised by the senior adult male in the group. His leadership is demonstrated primarily by greater sexual access to females at all levels of the female hierarchy, increased opportunities to be groomed by both males and females, and, in rare cases, increased access to meat obtained by other group members. He defends his position by displaying threats against subordinates and physical violence against challengers to his position. At some point, he is deposed by a younger, stronger male and drops down the hierarchy. Alliances between males and females are also present, and these tend to revolve around habitual grooming partners. There is some sense of female solidarity in that related females tend to spend more time with each other than with other females. Dominant females have similar politics but seldom intrude into the hierarchy of the males. There is, however, a sense of group in that unrecognized chimpanzees are in some cases driven away by the adult males. There are even reports of conflicts between unrelated groups of chimps.

By the end of the era—4000 BCE—politics takes on its more modern familiar meaning. Many people across the globe are now living in complex social formations characterized by hereditary leadership, significant social inequality, and impressive economic disparities between individuals and families. In some of these societies, rulers have the power of life and death over their subjects. In others, civil and religious authority is mixed, and rulers have the dual role of priest and king. In still others, religious authority challenges that of civil rulers. And in a very few of the societies of this era, true social classes are about to emerge. But in much of the world, especially those areas inhabited by hunters and gatherers, societies are more or less egalitarian and have few, if any, positions of permanent leadership. Between these extremes are those in which authority and leadership are tightly connected with kinship, lineage, and clan. Politics has become far more complex. There is good evidence that alliances between polities have become common. There is also internal politics, with factions within societies based upon competing economic and social interests. Although one hesitates to use the term “statecraft” to define the relationships between the polities of this period of the era, it is quite likely that the interactions between their maximal rulers would be very familiar to any modern politician.

The study of ancient leadership is mostly anthropological in nature, and scholars interested in it examine existing societies at varying levels of social and political complexity and use the results of their work to construct analogies of what politics in past societies might have been like. Those studying our most ancient ancestors use analogies derived from our close primate relatives to investigate probable forms of dominance and hierarchy and their changes through time.

In the nineteenth century, the anthropological study of non-Western societies was strongly evolutionary in tone. Influenced directly and indirectly by Charles Darwin, it was believed that human societies progressed through a series of stages from relatively simple to quite complex. Terms now seen as pejorative, such as “savagery” and “barbarism,”

Terms now seen as pejorative, such as “savagery” and “barbarism,” were used to describe societies that we now describe as hunters and gatherers, pastoral nomads, or village agriculturalists. Societies were thought to evolve through each of several stages.

were used to describe societies that we now describe as hunters and gatherers, pastoral nomads, or village agriculturalists. Societies were thought to evolve through each of several stages. At the end-point of the evolutionary hierarchy were Western industrialized nations.

Savages, the most basic stage, had no forms of permanent leadership, most of their politics were based upon kinship, and there was nothing like law as known

in Western societies. It was also thought that many contemporary “savage” societies, such as Australian aboriginals or North American Indians, were remnants of the earliest stages of human social, political, and cultural evolution. Barbarism was one step removed from savagery and defined by more “advanced” forms of social and political organization. Such societies had more permanent leaders and more rules and regulations that defined norms of social conduct, and political interaction was expressed through the competition of different kin groups or lineages as they jockeyed for social status and economic advantage.

This version of evolutionary thinking was roundly rejected by the anthropologists of the early twentieth century as they began to conduct ethnographic fieldwork across the globe. They found that there was no easy equivalence among societies labeled as savages, and furthermore, they realized that historical development created social and political structures within these societies that could not easily be attributed to their stage of development. Finally, these anthropologists rejected the judgmental quality of early evolutionist thought that placed Western societies at the pinnacle of social and political development.

Evolutionary thinking returned to importance in the mid-twentieth century and was described by its proponents as multilineal cultural evolution. Although change through time from simple to complex was recognized, these anthropologists made no value judgments about the progress each society had made and instead attempted to characterize social, economic, and political foundations as a result of adaptations to the environment. Thus, certain kinds of political or social structures should be found in hunters and gatherers living in resource-limited en-

vironments. Likewise, village-based agriculturalists, by nature of their subsistence practice, should have similar forms of economy, leadership, and kinship. Degrees of social and political complexity, then, were more about adaptation than a set of progressive stages of evolution.

This line of thinking led to another shorthand useful for the description of societies: bands, tribes, chiefdoms, and states. These four categories of society describe a continuum of complexity from simple to complex. Hunters and gatherers are generally seen as band-level societies, and for the most part, they are seen as egalitarian in social and political structures. The term “egalitarian” in this sense means that all leadership is situational and impermanent. A leader of a hunt has no authority over decision making about where the group should move to next. Status, often linked closely to leadership, is based upon gender, generosity, and relative humility. But there is no single individual or deliberative body that exerts authority or control over others.

Tribes are those societies in which lineages and kinship form the basis of leadership. Commonly, tribal societies have subsistence economies based upon agriculture or animal husbandry. Here, the headmen of kinship groups have political power. However, this power is highly limited and is based upon persuasion, not coercion. These headmen have real authority, but there is not necessarily a sanction against those who chose not to follow the headman’s decisions. Leadership is also compromised by competition between rival families, and thus internal politics becomes more complex as these groups seek alliances with other families or the inhabitants of other villages. Marriages are often used to create alliances, although these are fragile ties that can be easily rejected.

Chiefdom societies are those in which kinship groups are ranked. That is, one lineage may be recognized as the dominant one, and the headman of that lineage may thus be able to exert political power over subordinate lineages. All members of the dominant lineage are more highly ranked than all others. This does not equate to the formation of a dominant political class, however, as lineages may move up and down in rank depending on their economic and political fortunes. Factional competition between lineages is common, and chiefdoms are seen as unstable societies by many anthropologists.

Finally, states are those societies that have some form of hereditary leadership that can be transferred across generations. Fathers (or in some cases mothers) can pass on the right to rule to their children, who are recognized as legitimate candidates for rulership because they are born into the elite class. States typically have class structures wherein there is an elite stratum made up of highly ranked families. Below them are different classes based upon occupation or other social rules. Those at the top of the class structure are usually seen to have power over others. Codified sets of laws become more common, and these are used to adjudicate disputes and define rules of conduct. Alliance between noble families is quite important both within the state and with its competitors.

Although this is a useful four-part model, once again it became apparent that many societies did not easily fit into a single category. Some

hunters and gatherers—nominally bands—more resemble chiefdoms, for example, since they have ranked lineages. The reality is that societies are more complex and diverse than simplistic stage categories are capable of expressing. Nevertheless, these stages can provide insight into how politics might have been expressed in past societies.

—Mark Aldenderfer

■ Introduction: Forms of Leadership and Dominance in Primate Societies

In order to understand the possible structures of social life of our ancient ancestors, we must turn to analogies. Fossils and stone tools have their limits and are very poor guides to social relationships, especially in the very distant past. Modern hunter-gatherers are often used to construct analogies about what kinds of leadership strategies may have existed among our early ancestors, but the problem with these comparisons is that they are like comparing apples and oranges. Our ancestors were not fully human in terms of mental and cultural capacity, and thus direct comparisons are problematic and misleading.

Analogies derived from our closest primate relatives are often seen as more likely to offer some sense of the possibilities of what leadership strategies may have been like in the past. However, analogies are only guides to the past, and as such they must be used with care and caution.

Our closest living relatives are chimpanzees (*Pan troglodytes*), gorillas (*Gorilla gorilla*), bonobos (*Pan paniscus*), and orangutans (*Pongo abelii*). For chimps, bonobos, and gorillas, leadership is expressed through a male-based dominance hierarchy. For chimps, who live in multimale groups, there is a single adult male—the alpha male—who sits above all others. Because of this position, the alpha male has more mating opportunities and access to better resource patches. All other males in the group are arranged in a linear manner from top to bottom. All males, however, are dominant over females, who have their own hierarchy. Higher-ranking females have more offspring and have better ac-

cess to resources. Gorillas, in contrast, live in small groups composed of a single adult male, multiple females, and their offspring. Dominance is expressed between males when a group leader is challenged by another male.

Bonobos have a very loose male dominance hierarchy and very flexible social relationships in contrast to their cousins, the chimpanzees. Females may dominate males, and there is a strong bonding effect among female bonobos that limits the ability of any single male to become dominant.

Orangutans have social structures based upon female alliance and bonding. Except during mating season, males live a solitary existence within defended territories. Aggressive displays are common when males encounter one another. Females raise the young and often form small groups to resist mating attempts by subadult males.

Which, if any, of these analogies may be a good description of leadership among our early ancestors is difficult to determine. Many human hunter-gathering peoples have elements of both chimpanzee and bonobo social relationships in that while males tend to dominate these human societies (thus similar to chimps), so-called reverse dominance hierarchies limit the power of any single male (thus more similar to bonobos). Kinship in these human societies is flexible, much like the bonobos.

Chimpanzee and Gorilla Leadership

Dominance relationships among primates are primarily determined by their social structures. Social structure and dominance have both been extensively studied among chimpanzees (*Pan troglodytes*) and gorillas (*Gorilla gorilla*). Data on social structure and dominance for these species have been observed in the wild as well as in captivity. Aspects of dominance that have been of most interest to researchers have been how the initial rank is obtained, how it is kept, how it changes, and the influence that leadership has in primate relationships.

To understand how leadership functions among chimpanzees and gorillas, it is first important to understand the nature of their societal structures. The dispersal patterns, meaning which sexes migrate out of their natal groups and at what rate, affects how the dominant individual behaves in relation to its subordinates.

Chimpanzees congregate in multimale, multi-female groups. The composition of these groups is precisely as the title implies; many males and many females. Furthermore, chimpanzee groups have also been categorized as fusion-fission, which indicates groups that change due to individuals leaving and rejoining other groups. These groups are commonly made up of 20 to 100 individuals, but there have been many exceptions found in the wild and created in captivity. Chimpanzees are patrilocal, meaning that males tend to stay within natal groups, while females often leave to join other groups. Females often transfer when they are in mating condition and seek higher-ranking males. It is for this reason that male hierarchies tend to be linear and stable, while female hierarchies are more convoluted. Males are also dominant over all females of the group.

Gorillas have been documented to live in three types of groups: one-male, multifemale; multimale, multifemale; and all-male. For this reason, group sizes range greatly. In one-male, multifemale groups, the alpha, or silverback, is dominant over all of the females in the group. Gorilla groups tend to remain stable, but they are also one of the few known living primate groups in which both sexes leave their natal

groups. Males will sometimes range alone until they are able to join another group. They will leave their groups prior to breeding. Females, on the other hand, never travel alone.

Primates are born into a rank known as a dependent rank, which is the status they are able to maintain by virtue of who they are related to and thus who will give them support in conflict. Acquired rank is the rank an individual can hold independently. Among males, this is often determined by the strategic formation of alliances with other males to overthrow higher-ranking males or to further stabilize their own rank.

Chimpanzee and gorilla groups are similar in that males dominate females. The alpha male, the highest ranked of the males, will often rule by threat of violence. Threats are the most common form of aggressive behavior and rarely result in direct violence. Also, the alpha male has access to primary resources, such as estrous females and food. For example, when females are in estrous, the dominant males are able to copulate with females during the peak of their cycles. Subordinate males copulate with little significant difference in frequency but may not be able to access the females during the peak of their cycles due to threat of violence from dominant males. Subordinate males will often mate in seclusion, or hidden from view. Dominant males will copulate with females in more central locations of the group in view of all. This is also a similar situation with food in which subordinate males are more likely to share food with dominant males. Solitary males also copulate with females in groups, but this only occurs in situations where they can mate out of view of other males. Females have a looser hierarchy, but it is not as linear and clear as is found among males. In gorillas, the adult females spend more time near the silverback than they do with any other individuals in the group.

The most hierarchical differences arise when comparing multimale, multifemale chimpanzee groups and one-male, multifemale gorilla groups. Among chimpanzees, related females will spend much of their time grooming and bonding with each other. Gorilla females spend proportionately less time bonding with each other than they do grooming the silverback. The nature of intra-sexual relationships in each species leads to the

manner in which they have been observed to reinforce the dominance hierarchy.

There are various forms of dominance style ranging from the strict to the relaxed. In more relaxed dominance styles, the gestures and actions associated with hierarchical status may not be as prominent or may shift more frequently. In stricter dominance styles, the hierarchy is clearly established and reinforced often. Stricter dominance styles are more common to species in which one male and many females compose a group, such as some gorilla groups. The male may reinforce his dominance often through threat behaviors such as lunging or directly in the form of biting. Among chimpanzees and gorillas, dominance is reinforced through threats of violence. In gorillas, for example, dominance is sometimes shown by charging and chest-beating. Dominant chimpanzee and gorilla males guide the group's activities, frequently intervene in aggressive conflicts between subordinates, and

have priority of access to resources. Gorilla males, however, practice a stricter form of dominance. This is especially apparent in harem situations where one male must constantly reinforce his dominance. Since there is only one male to keep watch over various females, his leadership style must be much stricter than among chimpanzees. Among chimpanzees, leadership is more relaxed because the higher number of males requires more tolerance. Because chimpanzee groups require more cooperation between males, the dominance enforced over females appears to be more relaxed than that observed in the harem situations of gorillas.

■ Introduction: How Archaeologists See Early Social Complexity

Social complexity is a concept used by anthropologists to describe the range of occupations, kinship groups, factions, alliances, status positions, and leadership roles within a society. Modern industrial civilization is highly complex, with thousands of occupations, social classes, factions, and other social formations. In contrast, hunters and gatherers have many fewer social formations. Social complexity is thus a continuum ranging from the very simple to the very complex.

Social complexity, status, and leadership are highly interrelated but not always predictable. High social status does not necessarily imply political leadership. However, most socially complex societies do have permanent leadership positions that may have great social status as well. One of the interesting questions about the social evolution of our species is under what circumstances status begins to reliably translate into permanent political leadership. Put another

way, when do we begin to see indicators of social inequality, and under what circumstances do some people become more equal than others?

There are very few reliable ways in which archaeologists see early social complexity. For much of our evolution, until roughly 50,000 years ago, the signs of emergent complexity are very faint and are open to multiple, sometimes conflicting, interpretations. Indeed, it is only after about 15,000 years ago that archaeological indicators of social complexity become more common and less open to debate and challenge.

Using analogy as a guide, it is easy to see why complexity is difficult to see in the very early archaeological record of our ancestors. Most ethnographically known hunting and gathering societies, a category that describes most of the evolution of our species, are characterized by their egalitarian ethos. That is, no single individual is capable of forcing or compelling others to act against their own interests. Leadership is

highly situational as well. A healer may have real status in these groups, but this status does not translate into leadership in other social domains. Thus, a skilled hunter might be respected for his ability to kill animals but may be ignored when other decisions that involve the group are discussed. Finally, the range of status positions within these societies is quite limited as well. There may well be distinctions between people based on their age, gender, skills and abilities, and even charisma, but these differences in most circumstances do not lead to permanent leadership. The range of occupations is likewise limited.

Furthermore, all ethnographically known mobile hunting and gathering peoples have a strong ethos against accumulation and aggrandizing behaviors. That is, even when resources are abundant, efforts by some individuals to obtain more resources than immediately needed for daily consumption are strongly resisted by other members of the group. Hoarding is seen as an antisocial activity, and those who do so are chastised and ridiculed by other members of the group. Therefore, it is quite difficult to accumulate a surplus of subsistence or other resources that could be used to obtain other desired goods. Furthermore, since these peoples must move frequently to areas of more abundant resources, it is not possible to accumulate large numbers of objects simply because they cannot be carried.

For most of the evolution of our species, then, the material record reflects few social distinctions between individuals. Most objects recovered from deep antiquity reflect the subsistence quest or gender roles and as such say little about status distinctions.

The recent discovery of nonutilitarian objects, such as drilled shells and what is best described as art, which dates to between 60,000 and 100,000 years ago, has been used by some archaeologists to suggest that more socially complex groups began to emerge at this time. This is coincident with the appearance in Africa of transitional (or anatomically modern) *Homo sapiens*. These are real changes in the nature of the archaeological record, but their significance is not clear. The drilled shells are best seen as personal adornments, and at least to some archaeologists, they signal an enhanced ability to conceptualize the self and thus reflect cognition,

not expanded social roles. Interpretations of art are problematic as well. Most interpretations see art reflecting religious or spiritual activities, and thus their appearance at this time may well indicate a more formal role for religious practitioners. However, it is important to note that earlier material expressions of spirituality may not have been preserved in the archaeological record. Their absence cannot be assumed to be because they were not once part of the social fabric of our ancestors.

However, it is equally clear that there is no evidence of accumulation of subsistence resources or other material objects before 50,000 years ago, suggesting that while the range of social roles may have begun to expand, there was as yet no translation of these roles into permanent leadership positions. Insofar as can be read from the archaeological record, the societies of this period were still egalitarian.

More direct evidence for the emergence of social complexity, and perhaps social inequality, only begins to appear after societies begin to become more sedentary, which in most parts of the Old World only occurs after 12,000 years ago. Indicators of complexity include expanded storage of subsistence resources that go beyond the requirements of the household, the possession of extremely rare objects that would have been costly to obtain (many of which were used as personal adornments), and more prosaic evidence of early specializations of craft production. Rare costly objects signal the increased range of social contacts of an individual and their ability to trade for these items. This status-enhancing activity is seen by some archaeologists to be a very early form of social inequality in that these individuals have been able to overcome the egalitarian ethos and accumulate desired goods.

One of the most important lines of evidence used by archaeologists to track the emergence of complexity and inequality is the artifacts recovered from burials. For most of our prehistory, objects found with the dead reflected their gender. However, as complexity increased, people were interred with artifacts that more likely signaled their occupations or their ability to obtain, and then dispose of, these rare items.

Increasing Social Complexity to 4000 BCE

Between 2.5 million years ago, when early hominids produced the first tools, and 4000 BCE major changes in the social complexity of hominids occurred in parallel with developments in subsistence, notably food procurement, and technology. The evidence for early hominid social organization is limited due to relatively few archaeological sites, but even this indicates that hominids have always been social rather than isolated beings. By 4000 BCE highly organized and sophisticated societies had developed worldwide, mainly based on permanent agriculture and well-developed stone and metal technologies. In general, shifts in social structure tend to have occurred gradually over centuries or millennia rather than suddenly over mere decades. A key factor is mobility, which in turn is linked to food acquisition. Hunter-gatherers tended to be highly mobile, and although they are structured to a degree in terms of leadership and organization, their mobility limited material wealth, population size, and subsistence options. In settled societies leadership, or power relations, and wealth tended to be more hierarchical, while the individual's role in society was defined by her or his contribution to community operation, which is characterized by division of labor. Thus, the latter are more complex than hunter-gatherer societies. It is also likely that agrarian and urban societies were more flexible, which increased the chances of not only survival but also success. The transition from hunter-gatherer lifeways to agrarian-urban lifeways, can be considered to correlate with the traditional division between Paleolithic and Neolithic, dated to circa 10,000 BCE, involved a substantial increase in complexity. However, there are other periods of perhaps less pronounced but nevertheless significant changes in social complexity. For example, the

distinctions between the Lower, Middle, and Upper Paleolithic reflect increasing complexity in hunter-gatherer societies. In addition, a further distinction is recognized in northwestern Europe where a transitional phase, known as the Mesolithic, occurred between the Paleolithic and Neolithic.

The Paleolithic extends from 2.5 million years BCE to circa 10,000 BCE. Its subdivision into three overlapping stages is a convenient way of charting cultural changes including social complexity, but in common with all generalizations its limits must be acknowledged; most archaeological chronologies are generalizations that reflect a broad shift in social organization. The Lower Paleolithic extends from 2.5 million years BCE to circa 98,000 years BCE and incorporates the lifeways of *Australopithecus afarensis*, *Homo habilis*, *Homo antecessor*, *Homo erectus*, and *Homo heidelbergensis*. Three cultures distinguished by specific stone tool assemblages are recognized: the Oldowan, Acheulian, and Clactonian. The earliest hominids were scavengers, being opportunistic meat eaters as well as gatherers. Not a great deal can be discerned about their social complexity except that scavenging requires knowledge, such as where animals may die or be killed by other animals (e.g., in waterholes), and is most productive if a carcass can be shared before it goes rotten. Moreover, the adoption of meat eating by early hominids indicates the capacity to exploit a wider range of food types; omnivory is probably an indication of increasing social complexity, as it utilizes a wider resources base than carnivory or herbivory. The shift to hunting and the harnessing of fire were major changes in the social complexity of Lower Paleolithic hominids and mark a shift from a relatively passive role within the environment and ecosystem to an active role that positively seeks out resources. Evidence is scarce, but at the archaeological site of Boxgrove, West Sussex, England, bones and teeth of *Homo heidelbergensis* circa 500,000 years old are associated with butchered bones of large animals, including a rhinoceros, and an array of stone tools. This implies highly organized hunting through cooperation in groups. A further issue concerns the migration of *Homo erectus* out of Africa. Does its achievement reflect social

complexity, social problems such as resource scarcity, or curiosity?

The Middle Paleolithic extends from 300,000 years to 28,000 years BCE and includes the Mousterian culture. By this time *Homo neanderthalensis* had evolved, and by 200,000 years BCE *Homo sapiens* had evolved. The diversity of stone tool assemblages increased especially in relation to projectile points as arrow or spear heads were attached to hafts of wood. This would have enhanced hunting success and encouraged specialist craftspeople. The use of fire became widespread, and new ways of dealing with food emerged such as cooking, smoking, and salting, which reflect forward planning. Some groups practiced cannibalism. There is evidence for various burial practices, which could be linked with religion, care within communities, and several types of artwork such as jewelry and rock art. All point to the emergence of behavioral modernity, which are traits that are characteristic of modern humans and their recent ancestors; these include language, abstract thought, art, religion, and humor. Such traits are also indicative of increasing social complexity, though human groups probably continued to be relatively small and are generally thought to have been egalitarian. Once again, hominids in the form of *Homo sapiens* migrated out of Africa circa 80,000 years BCE.

The Upper Paleolithic dates from circa 40,000 to 10,000 years BCE and heralds the era of modern humans. Behavioral modernity had become well established. Numerous cultures, distinguished by specific stone implements, also emerged; stone assemblages attest to a wide variety of tools including axes, scrapers, blades, hooks, and needles. In addition, a wider variety of materials for tool making were employed, notably bone and antler. There is evidence for increasingly sophisticated hunting strategies involving fire, planning, and cooperation as well as a range of art types including many cave paintings depicting animals such as those found in Lascaux, France, and Venus figurines. Societies were becoming more sophisticated and diverse, though there is more evidence on which to base opinions than for earlier periods. There are also campsites reflecting some level of permanency and likely seasonal occupation. In-

creasing social sophistication is also reflected by the operation of trade. Although trade probably began in the Middle Paleolithic, it increased during the Upper Paleolithic as exchange networks for tools, shells, semiprecious stones, and possibly food developed. The Upper Paleolithic also witnessed the extinction of the Neanderthals circa 30,000 years ago. This is enigmatic but may be linked with the increasing dominance of *Homo sapiens*, which in turn may be linked with their increasing social complexity.

As the last Ice Age ended circa 10,000 years BCE, there were substantial changes in human activity and social organization worldwide. In northwestern Europe the Mesolithic, or Middle Stone Age, period opened and lasted until circa 4000 years BCE. Hunting and gathering persisted as the most important means of food acquisition, but evidence points to a varied diet incorporating seafood as well as plants and animals from forested and open habitats. Ritual or religious practices are indicated at some archaeological sites, and finds from Star Carr, Yorkshire, England, indicate seasonal occupation, fishing, and boating plus the use of a wide variety of stone, bone, and antler tools, while beads and amber reflect trade. How complex or otherwise Mesolithic societies were is a matter for debate. Certainly not much can be stated regarding social hierarchies or stratification, but Mesolithic societies were inherently successful, though they eventually relinquished nomadic hunting and gathering lifeways as agriculture spread from centers of origin to reach the European periphery by circa 4000 years BCE.

In the Near and Far East the first domestications of plants were taking place as precursors to the initiation of agricultural systems. This was the start of a new age known as the Neolithic or New Stone Age. The earliest domestications, of cereals such as wheat, barley, and oats and animals such as sheep, cattle, and goat, occurred circa 10,000 to 8,000 years BCE in the region of the eastern Mediterranean basin known as the Fertile Crescent, while rice was domesticated circa 8,000 years BCE in the Lower Yangtze Basin. Further centers of domestication and agricultural innovation developed in the Americas and Africa by 4000 years BCE. Why such innovations were necessary remains unknown but

must be associated with environmental and social factors; moreover, to invest so much effort in such a labor-intensive activity required considerable social organization. Societies became sedentary, with individual houses and storage facilities, and developed complex organization with a hierarchy and division of labor and expanded skills such as pottery production. They also planned and produced public monuments and buildings, the most prominent of which were the megalithic monuments of Europe for use by the general population. Ritual and religious practices were widespread and varied, as were burial practices. The Neolithic was an age of diversity and innovation with synergistic relationships with social complexity that, in turn, had profound ramifications for both environment and society.

Implications of Increasing Population Density Following Agriculture

The gradual implementation of agriculture in human societies from that which began 10,000 years ago, during what scholars call the Neolithic Revolution, had a significant impact on population density given the political and social organization necessary for the development of agriculture and the needs of growing populations. Hunter-gatherer societies, able to sustain small groups of pastoralists, needed huge tracts of land to follow herds and forage for and collect food, while newly developing agricultural societies needed smaller tracts of land for regular cultivation, which tended to create settled com-

munities with myriad needs to ensure survival and stability. Agriculture and irrigation encouraged long-term settlement in a particular region, whereas hunter-gatherers tended to follow an irregular seasonal settlement along their sojourns. Increasing population densities in agricultural settlements led to the development of more cohesive and integrative political and social systems in order to confront famines, reduce the potentiality of invasion, and establish legal systems for social stability.

The agricultural revolution allowed for the development of new polities amid the growth of settlements and the growing population density of these settlements. Many scholars have argued that agriculture and agricultural technologies allowed for the expansion of human populations as a result of food surpluses and thus allowed for the establishment of political, social, economic, and artistic developments in early settled societies. However, economist Ester Boserup, among others, argued that the opposite was true, that in fact preexisting population growth had triggered developments in agriculture and thus spurred on political and social developments amid agrarian settlements. Higher yields offered by settled agriculture allowed for the growth in population and the expansion of population density in the surrounding areas. Permanent field agriculture typically preceded the onset of political developments in urban settlements, given the need to create a cohesive governing structure for the growing population.

The onset of agriculture throughout various world regions allowed for drastic changes in societal organizations within an approximate 8,000-year period. These Neolithic farming villages emerged in Europe, East Asia, North Africa, South Asia, and Mesoamerica, with the oldest and more elaborate settlements located in the Near East, particularly in Palestine along the Dead Sea. The transition from hunter-gatherer societies to agricultural settlements and subsequent population growth contributed to the establishment of political organizations and trade networks to ensure the supply of goods and technology associated with agriculture. While this did not occur throughout the world at the same time intervals, it did occur within the larger period and led to similar developments throughout.

Growing populations in agricultural settlements also allowed for the establishment of occupational specialization in certain nonagricultural functions, such as metallurgy, arts, and other duties involving trade, not to mention religious institutions related to the emergent civic authority. Farming was relegated to certain members of agricultural societies, and thus other occupations were skill-specific in terms of manufactures and crafts. Technological advances related to agriculture and storage created the need for such crafts en masse (e.g., metallurgy and pottery) as routine specialized occupations rather than as sporadic developments, as with hunter-gatherer societies. Growing populations in agricultural settlements benefited from these new developments, as they created new venues for occupations outside of agriculture.

However, increasing populations also led to occurrences of bad harvests and the resultant famine, which in turn created a need for maintaining surpluses and storage facilities for said surpluses. These organized communities stored foods and manufactured material goods and eventually participated in trade. This led to the development of political organizations, which were maintained to ensure the prosperity and maintenance of crops for the populace and also to function as trading centers. The governing authorities were acceded legitimacy, as they were the ones responsible for administering agricultural surplus storage and preserving stability in the settlement. The growing complexity of the urban settlements allowed the functions and structures of the governing authorities to expand through time, encompassing far more functions than the mere administration of food surpluses. Moreover, social complexity through time allowed for the gradual development of the division of labor, as different social functions created different social levels for urban dwellers. Gender relations also became heavily bifurcated as certain occupations in society and within the household became associated with either men or women. Dwellings and housing, technological innovations, domesticated animals, and organized political structures all were a result of the relationship between settled agricultural communities meeting the needs of burgeoning population density in the transition from hunter-gatherer societies in the Neo-

lithic period. As wealth increased, populations became vulnerable to attacks by outsiders, and this allowed for more power to be accumulated by governing authorities, who gradually established their monopoly over violence and legitimate authority over protecting settlements and the surrounding territories.

Social Complexity in the Ancient Near East to 4000 BCE

The modern observer readily associates the concept “social complexity” with the higher-order complexity found in societies with class distinctions by which the early civilizations of Mesopotamia and ancient Egypt are characterized. Social complexity may also be an expression of a complex division of labor and a specialization of professional fields, albeit in the absence of social classes. The archaeological record of the Near East and neighboring Anatolia provides evidence for a bifurcation in the evolution of social complexity, one trajectory leading to complex society without social hierarchy and another where the emergence of social class distinctions is typical.

Social changes are a vital ingredient in human evolution. The transition from the organization of social relations in the communities of hunter-gatherers to levels of social complexity—as part of the “Neolithic package”—has had far-reaching effects on human society. For tens of thousands of years during their social history, humans lived in bands of hunters and gatherers. With the end of the Ice Age (that is, after ca. 12,000 BCE), living conditions in the Near East were subject to dramatic climatic changes that, in turn, created major challenges to the strategies of survival in the peoples of the region. The ecological conditions in the Near East had been those of a savanna toward the end of the Ice Age. Then, the seeds of wild grass and

other food crops were available in plenty and formed a considerable part of the hunters' diet. The climate changed and became colder and drier, and the availability of wild-grass seeds was more restricted. Because of such restrictions, the movements of hunters were limited to dwindling areas of resource abundance, and this spurred the development of sedentism.

The history of sedentism stretches over a considerable span of time, from the early experiments with planting wild seeds (as among the Natufian people in the twelfth millennium BCE) to full-fledged agriculture (as at Jericho in the latter half of the eighth millennium BCE). Among archaic hunter-gatherers there was an elementary division of labor, with hunting practiced by men while the manifold tasks of gathering and taking care of the children were the duties of women. This elementary division proliferates in sedentary communities to produce professional specialization and, eventually, full-time occupation with certain handicrafts. For example, craft specialization at Çatalhöyük in the seventh millennium BCE extends to the working of obsidian, which demands special-

ized chipping skills, and to small-size handicraft (i.e., crafting bead necklaces).

Evidence for an early specialization in handicraft is seen in the monumental structures at Göbekli Tepe in eastern Turkey, dating to the tenth millennium BCE. Monumental architecture requires specialized skills in masonry and sculpting but not necessarily a complex society or political leadership. The kind of specialization found in the communities of sedentary hunter-gatherers who built the first temples of humankind was not associated with the authority of a social elite. It is still widely believed that complex social structures are the precondition for the emergence of monumental architecture. The temple builders of Göbekli Tepe, with their sense for communal solidarity and elaborate skills, teach us otherwise.

The degree of social complexity in the agrarian community of Çatalhöyük that was founded around 7400 BCE and abandoned around 6000 BCE has been a matter of much debate. In the layout of the city there is no distinction between rich quarters with bigger buildings and others with smaller houses. Çatalhöyük has neither a

palace nor a central temple, but buildings are of equal size, and various sanctuaries are scattered throughout the city. Recent investigations into the grave goods of that settlement have revealed that there was no distinction between richer and poorer people or between male and female burials. The archaeological record does not show any evidence for a social elite that would have ruled one of the earliest towns of Anatolia.

Instead, communal life at Çatalhöyük was characterized by relative social equality between men and women. Also, when it comes to the part of revered ancestors for the constitution of lineages, the finds of selected male and female crania—separated from their skeletons—seem to indicate ancestry derived from both male and female lines. The kind of egalitarian society that has been reconstructed for Çatalhöyük had been identified earlier for the early agrarian communities in southeastern Europe.

Çatalhöyük, with its egalitarian community, provides evidence that the sustainability of communal life in an urban settlement with 7,000 inhabitants or more did not require the organization of social relations in a hierarchical order, as known from chiefdoms, and that the trajectory from bands to clans and to class society is not the result of a straightforward development in human evolution but rather one among several options.

Social complexity might have produced more differentiation and forms of political authority at Çatalhöyük, as known from chiefdoms, but such a stage of communal life cannot be identified for the Neolithic inhabitants of that city. In other areas, there was a trend toward the monopolization of economic surplus that was previously shared by the community as a whole, and this monopolization enhanced the establishment of political leadership, first of chiefdoms and later of kingship. The monopolization of economic surplus was most probably motivated by the control over offering goods for cult practices. Such an association is documented for the early temples of the Ubaid era at Eridu in southern Mesopotamia. Here, for the first time in human history, the chiefdom transforms into kingship and the political control over resources becomes large scale, resulting in the emergence of early statehood of the Sumerian era. The development of a complex society into the fourth millennium BCE—with

distinctions of social classes, a political elite, state organization, and bureaucracy—in the Sumerian city-states finds its parallel in predynastic Egypt of the Nagada period.

Social Complexity in Early Europe

During the period after the end of the Ice Age (ca. 10,000 BCE), called the Holocene, human populations in Europe experienced changes of their economy and social structures, and these processes of transition further increased with the advent of agriculture (ca. 7000 BCE). On the economic level, this was the shift from the subsistence system of hunter-gatherers to farming and, what concerns social structures, the shift from socially undifferentiated bands to communities with social stratification.

According to traditional approaches to this process of transition, this is described as an evolutionary trajectory from band via chiefdom to kingship, as if social development followed a straightforward path without alternatives. In this view, ruling elites in European societies made their appearance in the fifth millennium BCE, and kingship emerged in the second millennium BCE with the rise of the first state organization, the Mycenaean city-states.

Modern anthropological research has yielded insights that call for a revision of the static evolutionary-based model of socioeconomic transitions. What has been neglected in traditional approaches is the dynamic factor of human agency. In Holocene Europe, human beings shaped their cultural space ever more

THE MEANING OF THE CEMETERY AT VARNA

The ancient pre-Indo-European cultures of Europe were strongly affected by the process of Indo-Europeanization that unfolded during the fifth, fourth, and third millennia BCE. The influence of Indo-European culture was felt initially on the periphery of the Danube civilization (in the areas on the western coast of the Black Sea). The decisive thrust toward cultural Indo-Europeanization resulted from the third wave of Kurgan incursion (Kurgan wave III, ca. 3000–2800 BCE) when the people from the eastern steppe zone infiltrated into most of southeastern Europe and dominated the major areas where the Danube civilization once flourished.

In the northwestern Pontic region, the incursions of the steppe people produce permanent patterns of change. Judging from richly equipped graves, a new social elite makes its appearance at Durankulak (northeastern Bulgaria) around 4600 BCE, and 100 years later the tradition of burials also changes at Varna. The sudden appearance of great personal wealth, in a previously egalitarian context, may illustrate the fusion of worldviews as a result of intensive interaction between the local population and Kurgan traders from the northern Pontic region during the mid-fifth millennium BCE. The strict distinction between richly equipped male graves and female graves, which contain fewer goods, seems to be indicative of a society with a social hierarchy. However, in one of the major burials a male and a female were interred in a joint grave, which does not suggest gender difference in political power.

In one of the Varna graves, insignia such as a horse-headed scepter and other ceremonial items of political power were found that provide evidence of the spread of steppe tribes from the east to the west and in the Kurgan model of Indo-European origins is seen to reflect the first wave of Indo-Europeans from their homeland in the steppelands of the Ukraine and southern Russia.

Ornate burial from the Varna Cemetery in present-day Bulgaria. (Cordaiy Photo Library Ltd./Corbis)

Old European features prevail in lifestyles and religious imagery, while political authority appears to be represented by pastoral invaders. The graves near Varna yielded the earliest finds of gold objects dating to the mid-fifth millennium BCE. The technical skills reflected in the metal finds from the graves of Varna, containing the oldest gold treasure of the world, suggest that gold was worked much earlier in that region. Gold objects such as bracelets and ring pendants are found mainly in the Lower Danube area. It is noteworthy that gold was worked in southeastern Europe more than 1,500 years earlier than in Mesopotamia.

actively in their interaction with the natural environment. Human culture of the Ice Age was dominated by the struggle for sustainability, while Holocene communities in Europe saw humans engaged in the active management of their cultural ecology. Human agency promotes variability, and the local populations did not experience the same kind of shift to social complexity in all

areas at the same time. The overall picture of social complexity in early Europe is diversified, with various gravitations in different regions.

Contrasting with the traditional view of an intrinsic linkage of agrarian lifeways and social hierarchy are observations about social and economic equality in the communities of early agriculturalists. Evidence for this comes from

Anatolia (i.e., from Çatalhöyük, whose community flourished between ca. 7400 and ca. 6000 BCE) and from farming communities in south-eastern Europe. Climatic changes with a fall of temperatures and reduced rainfalls around 6200 BCE strongly affected the farming communities in Anatolia and hampered their development. But the repercussions were more moderate in Europe, where the pace of economic development was swifter than in contemporary western Asia.

Between 6500 and 5500 BCE, community life unfolded in southeastern Europe to reach the level of high culture or civilization, with institutions such as a complex layout for settlements, advanced technologies (i.e., pottery making, weaving), refined art and religious symbolism, metalworking (copper since the sixth millennium BCE and gold since the fifth millennium BCE), and sophisticated notational systems, including writing. The older name for this high culture is Old Europe, but it is currently known as Danube civilization. Comparative research on ancient civilizations has demonstrated that the fabric of the Danube civilization resembles that of the ancient Indus civilization (ca. 2600–1800 BCE). The most fundamental difference between these civilizations and those of Mesopotamia (the early Sumerian city-states) and ancient Egypt lies in the sociopolitical organization of the early agrarian societies. While ancient Sumer and predynastic Egypt knew the political institutions of ruling elite and related statehood, the ancient communities in the valleys of the Danube and Indus lacked such institutions.

In the Danube civilization, egalitarianism manifests itself in two domains: economic and social. Economic egalitarianism is manifested in extended trade relations whereby villages exchanged goods among themselves and with larger settlements. There is no evidence to show that any of the larger settlements would have dominated the economy of surrounding villages. In the context of economic egalitarianism, trade contacts evolved as relationships of mutual advantage, making the community a commonwealth or an ecumene. Among the preferred trade goods were obsidian, shells (spondylus in particular), salt, and copper. Social egalitarianism is reflected in the absence of a marked distinction between the social roles of the sexes in community life,

something that is typical of a society with social hierarchy. Equality between the sexes implies matrilinearity or matrifocality (with women as prominent figures in lineages), but this concept must not be confounded with the notion of matriarchy. According to modern anthropological research, cases of a sociopolitical dominance of women in historical societies are rare exceptions (e.g., the Naxi in southern China).

There were at least two basic models of sociocultural evolution that both inscribed in their constituents the possibilities of cultural and technological advancement so as to cross the threshold to the stage of high culture. One is the ecumene model, the oldest representation of which is found in Neolithic Europe (i.e., the Danube civilization). The other is the state model, well known from Mesopotamia and Egypt. Civilization as high culture did not originate from an exclusive and universal model of human evolution but rather as the result of differing trajectories that illustrate the overriding principle of variability, a principle that governs biological evolution as much as the evolution of institutions that emerged as the result of human agency.

In eastern Europe, Neolithic transitions produced a trajectory that did not favor agrarian life-ways or social egalitarianism. In the steppe zone of southern Russia, during the early Neolithic of the seventh millennium BCE a shift occurred from hunter-gatherers' subsistence to a pastoralist economy, with sheep, goat, and horse (later also cattle) as the basis of animal husbandry. Pastoralist society soon produced social stratification, forming a system of clans with strong leadership, territorial control over pastures, and a warrior elite whose importance increased in time.

In the course of the fifth millennium BCE, the pastoralists established contacts with the agriculturalists in the west. The subsequent history of contacts between steppe nomads and farmers is characterized by disputes over arable land (which farmers would claim for their economy but nomads used as pastures) and by militant clashes, culminating in the intrusion of pastoralists into southeastern and central Europe.

These movements of pastoralists have been associated with the migrations of Indo-European populations (Kurgan people) from the fifth millennium BCE to the third millennium BCE. The

Kurgan hypothesis of Indo-European migrations, advocated by archaeologist Marija Gimbutas, has been much debated and was neglected for some time, but it has experienced a reappraisal in recent years.

The people from the eastern steppe did not only establish their political supremacy over the agrarian communities in the west, they also introduced the model of social hierarchy and power relations, with the pivotal role of the ruling elite. Within a few generations, the former pastoralists became acculturated and adopted an agrarian lifestyle themselves. The history of western Europe from the fifth millennium BCE onward is the history of continual Indo-Europeanization and the construction of hierarchical societies.

Economics and Trade

For most of this era, economics and trade are mostly about the subsistence quest and production and consumption in the domestic sphere. It is only after 10,000 years ago that the trade and exchange of commodities such as stone, obsidian, and ceramics become a more important part of social life. By the end of the era, regional trade networks that covered large distances were common in the Near East, Mesopotamia, the Indus Valley, and East Asia.

Economics for our most distant ancestors was exclusively about the food quest. Individuals foraged for themselves, but mothers did share with their offspring and sometimes their close female kin. There is some limited evidence from East Africa that *Homo habilis* may have ranged over dozens of kilometers to obtain stone to make tools. Although it is not certain, it is highly likely that this stone was obtained during foraging trips for food.

More extensive food sharing with nonkin may be seen as a very early form of economics. In modern hunting and gathering societies, meat obtained by a hunter is typically shared among all of the people present at the camp. This form of sharing reflects the fundamental principle of reciprocity. In relatively simple societies, people exchange objects not so much for economic gain but for the social relationship that the exchange implies. Exchange creates obligations for future exchanges and highlights the social relationship between individuals.

The accumulation of objects or food in most hunting and gathering societies is seen as a breach of social mores and is strongly resisted. Those individuals who seek to have too much are often shunned socially or constantly mocked until they cease their drive toward possession. This also reflects the egalitarian ethos of these societies.

Ownership or personal possession is recognized, but the concept does not extend beyond the personal. In hunting and gathering societies, land is not owned in the common sense of the word but instead is open to all. Territory is often recognized, however, but the degree to which people from different social groups are excluded from it varies considerably.

As societies become more sedentary, however, the egalitarian ethos begins to break down, and the accumulation of food as well as nonsubsistence commodities begins to increase. Food storage is important in highly seasonal environments in which there is little to eat during the coldest months of the year. As societies in more temperate zones began to be more sedentary, families began to store food in larger quantities. Surplus food production—that is, more food is produced by a household than is required to feed it—could be used to obtain valued objects through trade and exchange or could be used to create debt obligations

with other families that were unable to produce enough food to feed themselves. Because of the reciprocity principle, these debts would have to be repaid either in kind or with labor. Some families, then, were able to use these repaid debts or this labor to further improve their economic standing. The surplus production of food meant that these families could then accumulate desired objects, thus enhancing their social status.

With the advent of more widespread reliance upon domesticated plants and animals, this process of accumulation, debt generation, and increasing wealth in the hands of a small number of families intensified.

There are numerous examples from ethnography in which land is held in common by a lineage or a village. The concept of private property seems to be a relatively late addition to the social lives of our ancestors.

However, reliance upon domesticated plants does not necessarily mean that land is owned by a single family. There are numerous examples from ethnography in which land is held in common by a lineage or a village. The concept of private property seems to be a relatively late addition to the social lives of our ancestors.

With increasing social complexity and the advent of village life, we begin to see signs of economic differentiation. In many

mobile societies, people make for themselves what they need to survive, including clothing, hunting equipment, utilitarian objects, personal ornamentation, and other items. Although some individuals may have greater skill than others in making specific objects that are then traded or bartered, for the most part households produce what they need. As villages become more complex, however, some begin to specialize in the production of goods or commodities, such as salt, wooden objects, and pottery. These goods are then traded in a number of ways, ranging from direct barter with producers to large market systems, where producers meet on a periodic basis to offer their wares to consumers in some central location. Itinerant traders may also serve to distribute goods between regions.

At the very end of the era, elites begin to support the production of what are best seen as luxury objects that are either displayed or presented as gifts to other elites. This is known as a prestige goods economy. Elites use surplus food production extracted from farmers to support this activity. Religious institutions as well use their wealth to support specialists to create objects of veneration.

—Mark Aldenderfer

■ Introduction: How Our Primate Relatives Made a Living

Nonhuman primates (NHP's), like humans, have evolved with a wide variety of methods to make a living. At the forefront of activities needed for living is obtaining

food. Some NHP's have developed complex mechanical and social methods for accessing resources, while others fill simpler ecological niches. Regardless of where they fall on this

spectrum of complexity, our primate relatives have evolved in a myriad of successful ways to make a living.

Foraging is the manipulation, collection, and consumption of food items. This is the most common method of obtaining food sources among primates. The only aspect of foraging more varied than the species among which it is observed is the vast array of forms it takes. Variation in both foraging methods and foods foraged for are based upon many factors. Among the more significant factors are the size of the animal, the physical structure of the animal, and its habitat. The animal's size impacts how much food it requires in order to survive. For example, a chimpanzee (*Pan troglodytes*) will need to invest more time in food acquisition than the much smaller olive baboon (*Papio anubis*). The animal's structure also determines which foods it may acquire. Anatomical limitations and advantages will determine not only its ability to acquire the food item but also its ability to manipulate it for consumption. For example, smaller primates are able to reach fruits found higher and on small tree branches. However, larger primates may have the strength to tear open tougher rinds to access seeds inside of some fruits. The animal's habitat also affects the availability and accessibility of food. Availability of food is dependent upon the suitability of the land for its growth, seasonal conditions, and topography. Primates are not only limited to what is available in their habitats but are also limited by where food patches are present. Seasonal changes affect when certain foods are available, which subsequently impact primate diets and foraging patterns. Topography affects where these food patches will occur as well as whether or not they are accessible to the primates. The high level of variation in the act of foraging is due to a large number of factors affecting the behavior as well as the wide range of species that have created adaptations to it.

Hunting is another method of food acquisition that is less common yet also highly varied. NHP's engage in hunting for insects and other live prey as both a solitary and cooperative activity depending upon the species in which it is being observed. The solitary aye-aye (*Daubentonia madagascariensis*) uses its elongated middle

digit to tap on trees in order to cause movement among the grubs within. Upon hearing the movement, the aye-aye chews into the wood and extracts the grubs with the same finger. Chimpanzees have been observed hunting cooperatively and strategically with other group members for red colobus monkeys (*Procolobus rufomitratus*) and have been seen to strategically block escape routes in the trees to trap their prey.

Tool use has been observed among NHP's in both foraging and hunting activities. Orangutans (*Pongo pygmaeus*) have been recorded habitually using tools while manipulating fruits for consumption. They have been observed using leaves to protect their hands while manipulating fruits with spiky rinds and have also been known to use twigs to scrape seeds from inside of fruits while partially open. Chimpanzees have been seen using branches to spear nocturnal primates known as lesser bushbabies (*Galago senegalensis*), which are sometimes found in tree hollows. In both cases, tools utilized were carefully selected for certain attributes and often manipulated to maximize efficiency for food acquisition.

Food Sharing in Primate Society

Food sharing is a trait that is observed in various species of primates. It is generally defined as the unforced transfer of food from one individual to another, most commonly close relatives. The study of food sharing among primates has been an important component of understanding reciprocal behaviors in primate social systems. Among nonhuman primates, food sharing has been most extensively studied among chimpanzees (*Pan troglodytes*). It appears that these interactions both shape and indicate the present nature of complex social relationships between individuals.

It was once thought that food sharing was an altruistic act between individuals. This was often thought to be the case when food sharing was observed between nonkin members of a group. However, further research has provided evidence that food sharing may serve to benefit the actor as well as the recipient. Food sharing occurs most commonly between related members, usually closely related kin, the most frequently observed being the transfer of food from mother to offspring. Among chimpanzees, mother to infant sharing was most commonly observed when the infant had trouble accessing or processing food. This was most frequently seen with fruits, especially when infants were unable to open hard shells or remove seeds from sticky pods. Frequently, a mother will tolerate an infant taking food from her hand, or she may directly offer it. This not only serves to increase the survival of the offspring but also contributes to infant learning. Through food sharing, the infant not only learns how to process foods and what is edible but also picks up on social cues involved with the transaction when it occurs between adults. This has been observed in younger primates, such as adolescent chimpanzees. Food sharing between adults tends to hold a highly social function. Which individuals share food can be indicative of social hierarchy, individual relationships, and relatedness. Food sharing most commonly occurs between individuals who are close in rank, bonded through sexual or allied relationships, or closely related. It has been observed that individuals are more likely to share food with individuals they are attempting to establish sexual relations with or individuals who assist them in some way.

Chimpanzee food-sharing behavior has been recorded intensively at Gombe in Tanzania and other well-known research sites in the wild. The majority of food sharing occurs from parent to offspring. Between adults, food sharing is predominantly initiated by males. This behavior is found in significantly higher frequency between males, with males to females, and with males to young or infant chimpanzees. It is found in the lowest frequency between adult females. This may also be indicative of the nature of chimpanzee culture, in which males form alliances and bond more than females do with each other. The reason for this structural trait is due to dispersal

patterns in this species. Males stay within their natal, or birth, group and thus form a more stable hierarchy. Females, however, often leave to join new groups in order to increase mating opportunities with other males. Males team up in order to successfully hunt young red colobus monkeys (*Piliocolobus badius*). While there are various theories as to specifically why the male chimpanzees share their food, especially protein-rich colobus meat, several trends have been found in meat-sharing following hunts. First, males are more likely to share meat with males who participated in the hunt. This suggests intrasexual social functions of meat sharing. However, this has also been observed in cases of sharing with other foods, such as fruits. Males not only shared with those after participating in hunts but also with males with whom they were attempting to establish bonds for future support. This is especially seen in males attempting to bond with higher-ranked males in order to reduce chances of harassment and increase chances of support in future alliances. Second, males were more likely to share meat with those who shared with them in previous situations. Reciprocal sharing has also been observed with other foodstuffs. In captive studies of chimpanzee groups, individuals who did not share food were also less likely to become recipients of shared food. In a sense, chimpanzees show awareness of which individuals are known to share and which are not. This applies to all individuals of a group regardless of age or sex. Third, sharing of meat has been seen to play a role in intersexual functions. Often dubbed the “meat for sex” hypothesis, males have been observed to withhold meat from begging females until after they have willingly copulated with them. Males are also more likely to share food, other than just meat, with females with whom they are attempting to copulate or have already established bonds. Currently, the primary motivation for food sharing among chimpanzees is still debated.

While chimpanzees remain the most frequently studied species engaging in food sharing, other species have also been known to utilize this social technique. Food sharing in the wild has been observed among the Callitrichidae family, which largely consists of marmosets and tamarins. These are New World monkeys, residing in South America, that are known for all

group members participating in infant care. Most observations of Callitrichidae food-sharing traits to date have been recorded among golden lion tamarins (*Leontopithecus rosalia*) and buffy-headed marmosets (*Callithrix flaviceps*). Among these species, processors were seen to give "food calls" soliciting younger group members to take food. Monogamous species within the Cebidae family have also been observed to share food with their mates and offspring. Within this family, the owl monkey (*Aotus trivirgatus*) and dusky titi monkey (*Callicebus moloch*) have been observed to share food in both wild and captive situations. Food sharing has been extensively studied in brown capuchin monkeys (*Cebus apella*) in controlled environments as well.

The study of food sharing among nonhuman primates is directly significant to understanding the role that food sharing may have played in human evolution. Observing practices of food sharing among chimpanzees, for example, may provide an example of how early hominids may have engaged in the practice. The tendency among all primates to share most with offspring indicates an innate drive to increase genetic fit-

ness by ensuring sustenance for the young. The social implications of food sharing have been studied by those suspecting that access to food may have influenced gender roles in modern human society. Many feminists believe that access to meat has played a large role in the formation of male-dominated societies. Whether this is truly the case or not has yet to be determined, but the importance of food sharing in primate evolution is indisputable.

■ Introduction: Food Sharing and Cooperation among Our Earliest Relatives

Human beings have adapted and thrived in a wider range of environments than any other animal. This distinction given to human beings is impressive because it has been achieved despite biological limitations and disadvantages. Humans are not the fastest or strongest animals, nor are they equipped with the most acute senses. However, they have developed one adaptation that has allowed them to survive and thrive as successfully as they have: cooperative behavior. There is a strong body of evidence to suggest that cooperative behavior and food sharing is an adaptation that existed among some of humanity's earliest ancestors. Three areas of anthropology support cooperation and food sharing among our early ancestors: primatology, archaeology, and cultural anthropology.

Studies of social nonhuman primates, particularly chimpanzees (*Pan troglodytes*), dem-

onstrate cooperative behavior especially in relation to food. Chimpanzees engage in cooperative hunting of red colobus monkeys (*Procolobus rufomitratu*s), working together to block escape routes in order to capture their prey. The meat is then sometimes redistributed among the other members of the group. Behavioral evidence suggests that if chimpanzees possess the cognitive abilities to engage in cooperative behavior and food sharing, early hominids most likely also had the capacity for such activity.

Archaeological evidence for cooperative living and food sharing among early ancestors exists in some sites of Olduvai Gorge, located in Africa's Great Rift Valley. In some sites of Olduvai Gorge, archaeologists have unearthed possible shelter remains, semiprocessed animal fossils, and stone tools that point to a strong possibility of cooperative living among our early

ancestors. These elements suggest a strong possibility of butchery sites, where early hominids would store tools and transport meat in order to process the carcasses. One stone circle found at Olduvai Gorge has been hypothesized to be the remains of a simple shelter. This simple shelter would have been utilized as a temporary camp while the hominid butchered or processed meat. A simple shelter would indicate that early hominids remained at the sites for a time period long enough to warrant the energy investment necessary to create such a structure. Many animal fossils excavated at Olduvai Gorge show cut marks from hominid tools, indicative of some kind of processing. Some of these fossils belong to fauna that would have been very difficult for a single hominid to acquire due to the size of the animals. This indicates that cooperative hunting and/or transport was required in order to bring the animal to the butchery site. Caches of stone tools matching the marks found on bones, thus processing equipment, have also been excavated at some Olduvai Gorge sites. By caching tools, as opposed to carrying these implements with them, our early ancestors would have saved energy. The practice of caching tools would also indicate that early hominids had the capacity to remember where the cache sites were located and navigate from kill sites to caches. This is a behavior that has been observed among chimpanzees.

If these are in fact butchery sites, then studies from cultural anthropology would lend further support of cooperative behavior and food sharing among our ancestors. These butchery sites bear a strong resemblance to temporary camps of contemporary foragers. In foraging communities, members almost always share their meat. Studies of foraging communities show behavioral patterns that lead to the creation of sites that leave evidence similar to the elements excavated in Olduvai Gorge.

Various lines of evidence from three anthropological subdisciplines point to the strong likelihood that our early ancestors engaged in cooperative behavior and food sharing. This evidence offers an explanation as to how humans became the most successful primate in the world.

Australopithecine Food Sharing?

The sharing of food resources beyond related kin is a behavior expressed in most human societies and is often considered a defining feature of humanness. Humans are also unique in the mammal world in the duration of the provisioning of offspring after they have been weaned from breast milk. However, in the context of human life history, which is characterised by a long period of maturation and reliance on adults, as well as basic evolutionary theory, the provisioning of offspring makes sense because it increases one's reproductive fitness. Among our primate cousins, food sharing also occurs between related individuals, especially mothers and their infants, and to a certain extent chimpanzees are known to share food outside of their own kin. Anthropologists are as yet unsure at what point in evolutionary history this became a critical component of hominin survival. In order to understand food sharing, scholars can make observations about the nature of this behavior in primates and modern hunter-foragers and use this to test hypotheses about fossil hominins; unfortunately, there is very little evidence to understand if and why this occurred in the australopithecine lineages.

Chimpanzees have the most diverse diet of the primates, relying on a variety of ripe fruits, leaves, seeds, and insects, and they opportunistically use tools to aid certain food-procuring activities (i.e., termite fishing with sticks, cracking open nuts with rocks). In addition, chimpanzee diets include cooperatively hunted vertebrates, such as monkeys and other small mammals, and although not reliant on this as a staple, hunting occurs consistently. The sharing of meat and herbivorous resources is quite different; mothers frequently share fruits, seeds, and other vegetation with their infants, but meat is generally shared between adults, including nonrelated individuals. Why might meat-eating encourage food sharing? Meat is both a valuable and mobile resource; the individual who is mainly responsible for procuring a kill (or appropriating it from

► THE DIVISION OF LABOR IN NEANDERTHAL SOCIETY

The division of labor in prehistoric societies is a topic that recently received a lot of attention from the archaeological community. However, the archaeological record left behind by Neanderthals contains little direct evidence of their social organization, gender role structure, or division of labor. Archaeologists thus rely on indirect information from ethnographical examples to construct hypotheses that can be tested against the archaeological data.

From studying the artifacts (primarily stone tools) and the faunal remains unearthed at Neanderthal sites, archaeologists have been able to establish that the overall Neanderthal subsistence strategy was based on hunting and gathering, much the same way our own species (*Homo sapiens*) survived for most of our species prehistory. We know that Neanderthals were very effective hunters based on the analysis of the animal species that composed their diet. The faunal remains indicate that Neanderthals regularly targeted large terrestrial mammals such as bison, various species of deer, and wild horses, thereby efficiently exploiting the resources of their environment. These remains also demonstrate Neanderthals' ability to exploit large animals in the extremely cold conditions of Ice Age Europe for over 200,000 years. Based on the analysis of the isotopic content of the Neanderthals' bones, it was determined that the Neanderthals' diet was largely composed of large herbivore proteins that regularly reached up to 85 percent of their overall diet. These different lines of evidence draw a picture of skilled hunters organized in highly mobile small groups able to adapt their subsistence strategies to the fluctuating climate of the Pleistocene. The need for cooperation during hunting expeditions tends to support the notion that some form of social organization existed during Neanderthal times and that some form of division of labor is probable.

From the study of the fossil record and now genetic studies, we also know that Neanderthals likely possessed a form of complex articulated language, similar to our own linguistic abilities. Such capacity for language is a prerequisite for successfully creating and maintaining strong and durable social ties. This capacity for language also supports the notion that Neanderthals maintained traditions over time. It is likely that some of these

traditions contained rules about social organization and division of labor.

To further identify what this organization may have looked like, archaeologists rely on ethnographical examples from living or recently documented hunter-gatherer groups. The premise of this analogical reasoning is that the mode of subsistence of any given human group impacts many other aspects of the group's social structure. Hunter-gatherer groups are known to possess a flexible social structure that allows them to quickly respond and adapt to changes in the environment on which they tightly depend. The social hierarchy of hunter-gatherer societies, however, is often limited since the social function of each group member is well established and does not require constant reinforcement based on authority. It is therefore safe to assume that Neanderthals' societies were organized around a loose social structure emphasizing the function and the skills of each group member. Prior to the 1960s and the rigorous use of ethnographical analogy, it was widely accepted that in most hunter-gatherer societies, men were in charge of hunting animals, while women and children were in charge of gathering and collecting plant foods, seeds, and tubers. This definition was later challenged by ethnographers emphasizing that in many hunter-gatherer groups, gender roles were not so strictly established. The main point was to remind archaeologists that a hunter-gatherer lifestyle requires the active participation of every group member and that women's roles were not restricted to child rearing and gathering plants. The relatively small part of plants and vegetables in Neanderthals' diet tends, however, to suggest that women did not play a major role in subsistence activities in Neanderthal societies.

More recently, the archaeologists S. Kuhn and M. Stiner used ethnographical analogy to conduct a study designed to assess what the division of labor may have looked like in Neanderthal societies. They relied on both ethnographical examples and archaeological data to confirm the hypothesis that men were likely hunting large mammals and thus procuring the bulk of the group's daily caloric intake. Women and children did not seem to have had a significant role. In some contexts, they may have participated in the gathering and hunting of small slow terrestrial animals (tortoise, snails, and

THE DIVISION OF LABOR IN NEANDERTHAL SOCIETY (continued)

shellfish), but their role was limited to supporting the male-dominated hunting activities and to occasionally participating in hunting expeditions. For Kuhn and Stiner, this clearly demonstrates the sharp contrast between Neanderthal and *Homo sapiens* social organization. In the case of our species, we created strong and complex social structures early in our evolutionary history. Such emphasis on social interaction is considered to be one of the most characteristic behavioral traits of our species. For example, the first sites occupied by *Homo sapiens* yielded artifacts with strictly symbolic and social functions. These objects included jewelry and ivory beads that were probably sewed onto clothing items. These decorative objects are often found in burials, thus indicating that they were meaningful and that they belonged to an individual, not the group. These artifacts most likely functioned as social markers to display special social status or the individual's

skills. None of these symbolic objects have ever been identified in Neanderthal archaeological contexts. This does not necessarily mean that such social hierarchy did not exist in Neanderthal societies but strongly suggests that their social organization was different and likely less elaborate than ours.

a lesser-ranking individual) can retreat with it to safety in order to guard it from others. However, while actively protecting a carcass it cannot be easily consumed. Therefore, it might be in an individual's best interest to first share the meat with others, and in some cases this follows along family lines. But more often than not the kill is made by a male and shared first with unrelated males, with smaller bits parceled out to females or juveniles. This situation may ensure that similar sharing is received on other occasions and may also be an agent of reinforcing social hierarchies. In fact, this is not so dissimilar from what we see in classic studies of contemporary hunter-forager societies such as the Ache and Hadza. The sharing of food resources is predominantly restricted to medium- to large-size mammals, which are actively hunted and distributed to both kin and nonkin depending on a number of variables: the type and amount of the resource, the likelihood of reciprocity, one's social status and the status of the receivers, the cultural meaning of the sharing event, and the way in which one's social group will perceive the sharer if he does or does not engage in sharing.

If meat plays a central role in food sharing in both chimpanzee and modern human societies, it

is not unreasonable to investigate the dietary adaptations of early hominins for evidence of meat consumption and the archaeological traces of this. Early reconstructions of hominin social behavior focused on dense concentrations of stone tools and mammal bones, especially at sites such as Olduvai Gorge. These were interpreted as home bases, places to which hominins returned with kills or scavenged remains in order to share with the wider community. Researchers now believe that many Early Stone Age accumulations were the result of the activities of many mammal species including carnivores and hominins, who were competing for these meat resources, but it is not clear exactly what the level of competition was between them. Furthermore, our investigations are confounded by the fact that we cannot be sure which hominin species made and used the stone tools purported to be used in the processing of meat resources. Gracile and robust australopithecines, early *Homo*, and *Kenyanthropus* were contemporaneous, and although most researchers favor a scenario in which *Homo* struck the first flake from a cobble core, this is not yet resolved, nor will it likely be.

Hominin morphologies provide more direct evidence for their dietary preferences, and they

do not indicate that australopithecines were obligate meat eaters. Craniofacial architecture and relatively large molars suggest that the australopithecines were adapted primarily for a vegetarian diet, one that was dominated by harder foodstuffs such as nuts and seeds that required a masticatory apparatus that could withstand high grinding forces in the robust species. The less specialized dentition of the gracile species, while still indicating that a substantial amount of vegetation was consumed, may however indicate a tendency toward omnivory. Isotopic studies infer that *Paranthropus robustus* may have consumed some animal material. However, it is the reduced molars, less the robust face and jaw and relatively larger brain of *Homo*, that indicate a probable transition toward consistent meat eating. Researchers may therefore conjecture that the australopithecines were primarily vegetarian but consumed and shared meat in a fashion similar to chimpanzees.

Recent advances in the application of agent-based computer modeling may help us understand what conditions favored the evolution of particular hominin diets and food-sharing behaviors. Such models infer that meat eating would have allowed *Homo* to meet their calorie demands in environments modeled after modern East African mosaic habitats. Furthermore, the increased patchiness of woodlands in the

Plio-Pleistocene may have favored an evolutionary scenario in which food sharing became critical to the survival of the group.

■ Introduction: The Ancient Household as the Primary Economic Unit

How do people make a living? That is, what is the range of variability in ways in which people obtain resources of all kinds? For our closest primate relatives, each adult animal is responsible for its own subsistence. Although chimpanzees share meat on occasion, this is rare, and such sharing is more the expression of social relationships than it is of subsistence requirements.

Mobile human hunter-gatherers, however, have a different modality of resource procurement. Here, the family, composed of a male-female pair and their offspring (the so-called

nuclear family), are responsible for obtaining resources for one another. A typical division of labor has females gathering plants and hunting small game, while males hunt larger animals. Children may or may not participate in food gathering. What food is obtained is shared among the members of the family, which could also include close relatives. Meat is shared more widely, however, as a gesture of social reciprocity. To fail to share meat is a serious social transgression, and there is real pressure to do so. In times of hardship, other resources may be shared with people from other families.

As people become more sedentary, the family becomes even more important. With growing dependence upon domesticated plants and animals comes a demand for more labor. Children often tend animals, weed plants, and participate in the harvest. Families also become more complex as well and may include other adults defined as family members through new forms of kinship (extended families) and who work together to obtain resources. Surplus subsistence production—that is, more food than is required to feed the family or prepare it for the next season—is often held within the family unit. This may lead to disparities of wealth between families, and many anthropologists see the accumulation of surplus as crucial to the development of social inequality and the formation of more complex societies.

Through time, then, we see a transformation of the subsistence quest from individuals to nuclear families to large extended families. Although the transition to large extended families as engines of economic growth are clearly associated with the onset of sedentary life and eventually reliance upon plant and animal domesticates, the transition to more widespread food sharing within the nuclear family is not so well understood. Indeed, exactly when families appear is a point of debate within the field. Once they are created, however, they become essential to societal reproduction and longevity.

—*Mark Aldenderfer*

Evidence for the Division of Labor in the Upper Paleolithic

The Upper Paleolithic era spans a time period from around 45,000 years ago until approximately 10,000 years ago. It has numerous informal monikers due to the enormous wealth of artifacts, leading to an even larger trove of hypotheses regarding the many human behaviors and advances made during this time. Tools of this period are key to unearthing the flurry of activity that seemed to occur at this time. This particular time period, especially the transition between the Middle and Upper Paleolithic, marks a boom in archaeological evidence for technology and the division of labor. Division of labor is a major indicator of development, since it is characterized by

cooperative specialization. For this reason, it is important to determine when the division of labor began in human history. While the existence of a division of labor at such an early point in hominid history is still debated by some, artifacts from sites all over the world point to at least a strong possibility of the development of a division of labor occurring as far back as during the transition between these eras.

Technological advancements made in the Upper Paleolithic era allowed for increased quantity and efficiency of tool production. A wide variety of tools have been excavated from sites dating from the Upper Paleolithic. The formation of these tools, particularly blades, has been a major topic of discussion among archaeologists. One of the most fascinating findings from this era is the discovery of numerous thin, relatively uniform blades. This indicates development in the sophistication of tool making and thus increased manners in which our early ancestors could manipulate raw materials. Among the most significant of these blades discussed are prismatic. These are thus named for their shape, which displays tapering narrowness on either side. Prismatic blades were produced from methods known by archaeologists as Levallois and Disk Core technologies. The Levallois and Disk Core techniques employed the striking of flakes from a prepared flint core. These methods were widely utilized during the Upper Paleolithic and grew increasingly refined over time. Another highly significant technological advancement made during the Upper Paleolithic was the production of burin blades or microburin. This is a technique that allowed our early ancestors to produce very narrow blades. These blades were useful for gouging and engraving bones. From these bones, bone needles were then created. Bone needles meant that clothing could also be manufactured that was more closely fitted and thus more effective for thermoregulation in frigid temperatures. These two major technological advancements contributed to the explosion of tools and artifacts found in archaeological sites of the Upper Paleolithic. The development of such sophisticated techniques as well as their consistent employment supports the notion of a division of labor existing during the Old Stone Age. The existence of many blades and needles manufac-

tured from the same techniques would indicate the existence of specialists among our early ancestors, able to manufacture uniform tools and products.

Increased sophistication of tools also paved the way for more efficient hunting, thus giving our ancestors an edge in survival. One of the most advanced hunting implements of this era is the atlatl. The atlatl gave hominids the ability to hunt using sharpened projectiles. The darts are flung from a leather strap, which rests over the user's shoulder. The invention of the atlatl increased not only the distance from which a target could be struck but also the accuracy with which it could be struck. The atlatl was more accurate than throwing projectiles simply by hand. This was advantageous for widening the variety of game that could be utilized as food sources. Again, the manufacturing of such tools indicated

the presence of specialists since many were uniform.

Cultural artifacts also point to specializations of trades and skills. The study of art during this time is highly significant because art shows movement toward specialization. Cave paintings are among the most-discussed topics regarding the Upper Paleolithic. There is also evidence for shamanism, especially in sites where ritual burials are evident. Specializations for cultural activities further support the existence of a division of labor in the Upper Paleolithic.

■ Introduction: The Social and Economic Meaning of Exchange

Ever more archaeological, anthropological, and linguistic evidence is being accumulated to demonstrate that peoples of the Old World were engaged in long-distance trade contacts and intercultural relations much earlier than has hitherto been believed. Nothing speaks against the assumption that a network of trade relations had been established within Anatolia and between this region and Mesopotamia at an early date. Trade relations already functioned with certainty during the times when the ancient accounting system, used by Samarran and Ubaid and later Sumerian traders in the Near East for counting commodities, came into use in the eighth millennium BCE.

It is obvious that the incentive to engage in the exchange of goods is motivated by multiple interests, which may be practical as well as non-practical. Ecological conditions may trigger processes of an intensification of contacts between distant groups of people. For instance, the fourth millennium BCE saw a climatic change in Anatolia, the Near East, and Mesopotamia. As a result,

weather conditions became drier, and agriculture became more difficult in the areas of early farming. The human response to this change was the intensification of the use of arable land by means of irrigation, the improvement of agricultural techniques, and the initial establishment of cultural and trade links.

Exchange has a broad meaning that encompasses both the exchange of commercial goods as an act of trade and the exchange of gifts. The former way is associated with items of material and practical value; the latter way is linked to items that carry symbolic and sociocultural value. In principle, any kind of exchange may have both social and economic significance, although preferences for one or the other may relate to certain materials or goods, as appreciated by people in different communities.

Obsidian is among the oldest known items of material value that has been traded since ancient times. Obsidian had already been traded across Anatolia thousands of years before the founding of the oldest town in Anatolia, Çatalhöyük,

around 7400 BCE. Evidence for early trade relations comes from this site, where obsidian, as a trade good, from quarries near two volcanoes in southern Cappadocia is attested for the seventh millennium BCE.

Altogether, seven different industries relating to the production of obsidian artifacts have been documented for the community at Çatalhöyük, which attests to the specialization of handicraft in an early phase of agrarian society. Moreover, the distribution of obsidian raw material at Çatalhöyük points to exchange in the hands of specialized traders. The wide range of items made of obsidian suggests that the significance of this material reached far beyond the practical into the social sphere and suggests a relation to social identity, given its use as a razor for grooming and scarification.

Perhaps the most prominent items with symbolic significance in the exchange networks of the Neolithic were figurines. Actually, it was their fragments that were exchanged in acts of fragment enchainment. Pieces of broken figurines have been found in numerous settlements of the Danube civilization dating to the sixth and fifth millennia BCE. Among the early agrarian population of Europe, there was a widespread custom to break figurines into pieces after rituals and ceremonies in which they had played a central part. Obviously, those pieces were believed to be infused with spiritual energy, and consequently they were considered precious. The broken pieces were not discarded but instead were given as gifts to friends, kin-folks, and trading partners. This habit explains why the pieces of one and the same figurine could travel in different directions and find keepers at various distances from the place where the sculpture had been made.

Such customs of using figurines and/or pieces of them in gift exchange were induced by a spiritually grounded worldview and intended to sustain social relationships in community life. Beyond the Neolithic era, this kind of gift exchange was popular in classical Greek civilization, among the Etruscans, and in ancient Rome. In some regions of the world, gift exchange to sustain social bonds has been practiced since ancient times up to the present, such as in the local Melanesian cultures in eastern Papua New

Guinea and adjacent islands. The repeated custom of exchanging ceremonial gifts over the whole life span is called *kula*.

Upper Paleolithic Exchange Networks

The development of exchange networks during the Upper Paleolithic (approximately 50,000 to 10,000 years ago) is indicative of the degree of change that occurred in human societies during the long-term transition from hunter-gatherer to agricultural settlements. Moreover, the establishment of exchange networks is indicative not only of the type of subsistence of early human societies but also of the growing connectedness between such societies in proximity to each other for the distribution and exchange of goods. Archaeological evidence indicates that goods such as marine shells, lithics, and other raw materials were exchanged over distances of several hundreds of kilometers in some areas of Afro-Eurasia. This reflects the level of complexity that characterized these early societies during the Upper Paleolithic through the onset of specialized crafts and ubiquitous technological innovations, which percolated across much of the world through these exchange networks.

The development of social and economic organization of early human societies during the Upper Paleolithic, particularly the ubiquitous hunter-gatherer bands that characterize the period, allowed for the establishment of exchange networks. Moreover, they are also indicative of evolving human behavior and cognitive capacity in that they illustrate the ability to understand the idea of value and exchange. Raw materials such as mammoth ivory, amber, marine shells, and elk teeth were exchanged in Upper Paleolithic Europe. These were later crafted into dec-

orative objects or implements for composite tools. While the prevalence of local raw materials used in manufactured goods found in archaeological sites is indicative that most items were collected from local sources, the use of valuable raw materials that were highly valued, as they were of higher quality and used for more ostentatious decorative purposes rather than more practical applications, is evidence of exchange networks.

There is evidence that exchange networks preexisted the Upper Paleolithic period, given that certain sites indicate that small quantities of stone from as far away as 74.5 miles (120 kilometers) were exchanged in western Europe. While much of the raw material for lithic industries was locally extracted, a small percentage of stone was in fact exchanged with other early human societies during this period. Evidence also suggests that late in the Middle Paleolithic, growing percentages of imported stones vis-à-vis local raw materials were brought from greater distances. In one instance in eastern Europe, some materials were found to have been brought from approximately 186.4 miles (300 kilometers) away, indicating greater distances in the emergent exchange networks of Eurasia. Moreover, some scholars suggest that sources of flint in eastern Europe were more vastly dispersed perhaps due to a colder climate, which necessitated longer distance rather than shorter-distance exchange networks such as those in western France. Early humans would have had to migrate much more frequently in such ecological conditions and had greater contact with other groups during their sojourns, thus establishing exchange networks over vaster distances. In contrast, shorter-distance exchange networks, such as those found in France, indicate that the prevalence of certain materials in more hospitable climates did not necessitate longer distances for trading such goods.

Lithic assemblages found by archaeologists at various sites in Europe, Asia, and Africa suggest that by the Upper Paleolithic, the percentage of local raw materials, while prevalent in tools and implements, included larger amounts of stones exchanged from vaster distances. In Germany, Gravettian sites had an estimated 95 percent of their lithic artifacts composed of

stone from within a radius of 15.5 miles (25 kilometers), with the rest from outside that perimeter. In contrast, in French Upper Paleolithic sites there were higher percentages of nonlocal flint in the lithic assemblages found. In central and eastern Europe, much like in the Middle Paleolithic, there is evidence of long distances in exchange networks but in much larger percentages of nonlocal stones for lithic implements. In some cases, in eastern European assemblages some perhaps came from distances as far as 186.4 to 260.9 miles (300 to 420 kilometers) from the archaeological sites where these were found. This indicates that long-established exchange networks continued from the Middle to the Upper Paleolithic amid the increasing complexity of human societies during this transition.

The Importance of Agriculture for the Expansion of Trade

A precondition for agrarian ways of life is sedentism, which enhances the construction of solid houses for a continuous presence of their inhabitants. The houses of agriculturalists provide more space than dwellings in the campsites of hunter-gatherers (foragers). Sedentary agriculturalists develop their capacities for the storage of grain and other items so as to guarantee the provisioning of food from one season to the next.

Storage capacities are enhanced with the spread and specialization of technologies relating to the making of pottery and ceramic vessels. Depending on the quality of the soil and on weather

conditions the surplus of agricultural production may vary, but it is the key to socioeconomic advancement in agrarian communities and calls for trading and exchange. Trade may even assume a decisive role for sustainability of communal life. In those areas of the Old World where agrarian societies under the auspices of social and economic equality were established (i.e., in south-eastern Europe in the sixth millennium BCE and in the Indus Valley in the third millennium BCE), intensive trade for mutual advantage was the backbone for the relations between communities in bigger and smaller settlements.

The early agrarian communities traded agrarian surplus among themselves, but in order to enlarge the range of their exchange and the spectrum of commodities agriculturalists would engage in trade with their hunter-gatherer neighbors. The findings from comparative ethnographic research show that the relationships of agriculturalists and hunter-gatherers are, as a rule, friendly because there is no agenda of conflict over terrain. The agriculturalists would not compete with hunter-gatherers over the exploitation of the forest, nor would hunter-gatherers be interested in the fields for plant cultivation. Comparative research has also produced insights about prestige relations. Hunter-gatherers would consider agrarian lifeways to be more prestigious and would prefer commodities offered by agriculturalists for that reason.

Prehistoric scenarios of trading in the contact zone separating the area for plant cultivation from hunting grounds have been studied for southern and northern Europe. The context of contacts between Indo-European agriculturalists and Fennic hunter-gatherers in the Baltic area is illustrative of how exchange networks develop and expand. Agriculture spread into the region south of the Gulf of Finland from the third millennium BCE onward, gradually expanding in a west-east direction. In the eastern Baltic region, the frontier of agriculture remained stable over many hundreds of years. The Baltic agriculturalists engaged in trade with Fennic tribes on a basis of mutual advantage in a balanced reciprocity.

Prestige goods from the south that were traded to the people of the north included pol-

ished stone axes, pottery, bone combs and rings, cattle, and grain. The items that the agriculturalists received from the foragers in exchange for their commodities were furs, arrowheads, seal fat, forest products (berries, herbs, edible roots), and amber. This contact expanded over vast areas in the Baltic and eastern Europe, establishing connections for cultural and technological innovations. Trade enhanced social contact, and in the course of time, social relationships were also established, with a trend of forager women marrying into the lineages of agriculturalists.

Gradually, the hunter-gatherers with social bonds to the people in the south would acculturate and adopt agrarian lifeways themselves. The transition to farming in the eastern Baltic may have lasted over a longer span of time, between 700 and 1,500 years. In the zone bordering farming areas, bilingual and bicultural communities were established. It may have been the members in these communities who controlled the exchange of goods and ideas both ways. These prehistoric contacts can be traced by the linguistic borrowings of Baltic origin in the modern Baltic-Finnic languages, and these are loanwords in the terminology of kinship relations (e.g., Finnish *morsian*, "bride"; *sisar*, "sister"; *beimo*, "tribe") and of body parts (e.g., Finnish *kaula*, "neck"; *hammas*, "tooth"; *reisi*, "thigh").

The Growth of the Obsidian Exchange Network in the Near East

Obsidian is a black, green, or red rock of volcanic origin. Its noncrystalline structure is due to rapid cooling of lava, which gives it a glasslike attractive appearance. It is easily worked by flaking or knapping, and when fractured it has sharp edges. Such properties made it attractive to Stone Age societies for making a range of tools and projectile points as well as for mirrors, jewelry, and decorative purposes. Moreover, the obsidian produced by each volcano, and even each eruption, has distinctive properties or chemical signatures, notably trace metal and isotopic characteristics. In combination with dating controls, these characteristics have been used to reconstruct ancient obsidian trade networks. The obsidian was initially carried by individuals on foot and later by ship and was traded as the raw material and the finished product.

Among the oldest obsidian tools are flakes and blades from the Red Sea coast of Eritrea, which are at least 125,000 years old. However, major exchange networks began to appear from circa 12,000 BCE. This was a time when hunting and gathering were becoming increasingly organized and the initial stages of plant and animal domestication were occurring prior to the beginning of agriculture and the start of permanent settlement; all mark the increasing social complexity of Upper Paleolithic and Early Neolithic societies. Many sources of obsidian have been identified. Sources in Turkey are widespread in Anatolia and Cappadocia, while the obsidian of the islands of Pantelleria, between Sicily and Tunisia, and Lipari, between Italy and Sicily, supplied Tunisia and Sicily plus many other locations in the central and western Mediterranean via sea trade. Both islands supported well-developed Neolithic cultures as a result. Other sources in Transcaucasia (modern Georgia and Armenia) were also used but mostly locally. However, the sources in Cappadocia and Anatolia are especially significant in terms of a trading network in the eastern Mediterranean. The obsidian trade also enhanced links between settlements and contributed to the wealth and

development of settlements. These trading links were not confined to obsidian insofar as other commodities, such as crop plants, domesticated animals, and pottery were also exchanged, and equally importantly, ideas were transmitted.

At about 12,000 years BCE when habitats were still open, obsidian from two major sources, Göllü Dağı and Nenezi Dağı in Cappadocia, central Turkey, and deposits at Nemrut Dağı and around Bingöl in Anatolia, western Turkey, was traded several hundred miles along two major routes. As well as spreading west to the Sea of Marmara, Cappadocian obsidian crossed the Taurus Mountains to the Euphrates and into the northern Levant, and Bingöl /Nemrut Dağı obsidian was taken southwest along the foothills of the Eastern Taurus Mountains to the Tigris Valley and what is today Iraqi Kurdistan. As climate ameliorated, Cappadocian obsidian penetrated farther south into the Jordan Valley. By 9500 BCE when settlements were becoming permanent and agriculture was beginning, the volume of traded obsidian increased, and there was a degree of coalescence between the two sources, notably in the Middle Euphrates Valley. Within a millennium the trade had further expanded, probably in response to increasing demand from growing settlements and populations in the region, which were supported by well-organized food production. Notable developments were the shipping of Cappadocian obsidian to Cyprus and the extension of the land trade route to the Negev as well as the trading of Bingöl obsidian farther southeast to the Zagros Mountains. There is evidence that several urban centers controlled the obsidian trade including Çatalhöyük, Abu Hureyra, Bougras, Ain Ghazal, and Basta. Çatalhöyük, located on the flat plain of Anatolia, which was an important agricultural region, was noted for trade in general; shells and various semiprecious stones exchanged hands there, but the obsidian trade appears to have been prominent. Well-crafted arrowheads and spearheads have been found, and the importance of obsidian in the economy is reflected in the presence of a wall painting that depicts the eruption of the nearby volcano Hasan Dağı. Moreover, the abundance of shrines in the city to a goddess of similar image may indicate a close link between religion and obsidian trading.

It is possible that the obsidian itself was considered to be a sacred stone with divine power. Çatalhöyük's size, significance as a regional center, and wealth would have been due in large part to the obsidian trade. By 7000 BCE pottery production was developing, new settlements were being established throughout the Near East, and existing settlements were flourishing. A new obsidian trade route opened up along the coast, and obsidian ownership increased significantly. Only with the advent of metallurgy several millennia later, which provided durable and sharp implements, did the obsidian trade decline.

Exchange Networks in Neolithic Europe

The exchange of goods, the beginnings of trade, and the emergence of systems of material value already date to the times of the Upper Paleolithic. However, it was during the Neolithic era that trade relations became more organized and developed into exchange networks, including far-distant or interregional trade. With the rise of horticulture and agriculture, goods and exchanged items became more diversified, including not only things of material value but also items that carried symbolic meaning, with significance for social bonds between kin groups, lineages, or communities that were engaged in trade over longer distances. A diagnostic item with religious significance for a network of gift exchange are female figurines and/or their pieces that are scattered throughout the Neolithic communities of the Danube civilization.

Among the first materials that were traded in the modern sense of the term was obsidian. According to experts, the most outstanding prop-

erty of obsidian is that properly worked blades are sharper than a knife made of metal. The area of origin of local obsidian can be pinpointed on the basis of its chemical composition ("signature"). Evidence for trade of obsidian over longer distances comes from Anatolia and from central and southeastern Europe. Already in the seventh millennium BCE, obsidian was transported from sites in Hungary and Slovakia to the Balkan region. There was another obsidian route leading from the Aegean coast farther inland. The area of origin of the Aegean obsidian is Melos, one of the Cycladic islands. Finds of obsidian from Melos on either side of the Aegean Sea are proof of sea trading in the Early Neolithic.

Throughout the ages, the major river systems in Europe have served as transport routes for people and goods. This is true for the Rhine and the Danube as much as for the Dnieper and the Volga. The early obsidian trade route from central Europe to the south went down the Tisza River into the Danube and as far as the Black Sea at a later date. The southern route from the Aegean coast was directed overland into the Danube Valley. Of all the Neolithic trading centers in the Balkan region, Vinca (south of Belgrade in Serbia) was the most important, linking the main route along the Danube with side routes along its tributaries. Vinca was founded around 5500 BCE, and the trade route system remained intact until circa 4000 BCE.

From the Aegean coast, a much-appreciated trade good—spondylus shells—found its way into the Vinca region and beyond. It was not only the big size of those shells that impressed Neolithic people but also the spiral structure of their core. Spondylus shells were worked to produce bracelets, pendants, and receptacles for special use such as cult vessels. The network of trade relations for this item was amazingly vast, and one can follow the spondylus trade archaeologically over nearly 1,864 miles (3,000 kilometers).

Obsidian and spondylus shells are durable materials. Therefore, their routes of distribution can be easily studied. However, it is not always easy to ascertain which were the goods traded in exchange. In the case of pottery and ceramic ware, these items tend to be widely strewn over large areas. Pots from the Vinca region have been found at distant places as far as southern

Anatolia. The exchange of perishable goods can only be inferred from comparisons with later periods for which documentation is available. Among the goods that were traded by late hunter-gatherers and early agriculturalists were furs, animal fat, the meat of domesticated animals, and surpluses of grain and fruits.

Metalworking started in the Balkanic region, and this new technology spread to the north and into the steppe zone of eastern Europe. The oldest metal that was worked was copper (since the sixth millennium BCE), later followed by gold (since the mid-fifth millennium BCE). The beginnings of metalworking and of the distribution of items made from metal date back in time prior to the advent of Indo-European populations. Linguistic evidence for the time depth are the terms for copper and for the generic terms for “metal” in Greek (i.e., *kbalkos*, *metallon*), which are both of pre-Greek origin and were adopted by the Greeks from the ancient pre-Indo-European population of southeastern Europe.

The use of metal signaled the beginning of a new era when stone tools were gradually replaced by copper tools. The era is called Chalcolithic (derived from the ancient Greek term for “copper,” *kbalkos*) or Eneolithic in modern terminology. Copper, especially in the form of ore as raw material, was traded throughout southeastern Europe. While copper was traded in considerable quantity (in the form of ore, metal scrap, or manufactured items), gold was of much rarer occurrence and may have served, from the beginning, as an item signaling social status.

Salt was a much-needed and much-appreciated commodity that was available in eastern Bulgaria and in Transylvania (northwestern Romania). Recent archaeological excavations have uncovered large salt deposits in the area of Provadia on the banks of the Provadia River west of Varna. The exploitation of the local salt demanded the development of special technologies of salt extraction from the rock-hard deposit and of the production of ceramic vessels with specialized functions.

The prehistoric settlement near the site was fortified, obviously to protect the area of salt exploitation against outsiders’ incursions. The con-

trol over salt and of the trade with it as a source of prosperity for the local community might have been the decisive incentive for steppe people to make incursions into the Varna region and establish themselves as a social elite over the local population. There might have been a connection between the prosperity stemming from the trade with salt and the advancement of metalworking (i.e., of gold) in the region. The oldest artifacts made of gold known in the world have been unearthed from a prehistoric cemetery near Varna. These artifacts are plates made of hammered gold in the shape of animals (i.e., cattle) and spirals.

During the transition from the Eneolithic to the Bronze Age (late fifth millennium BCE), the significance of exchange networks increased. Trade, including prestige goods made of metal, became a major form of subsistence for certain local groups in the contact region of western agriculturalists and pastoralists from the Eurasian steppe.

War and Diplomacy

The antiquity of conflict, warfare, and diplomacy in the course of human evolution has yet to be defined with clarity. For most of our species' evolution, terms like "war" and "diplomacy" are hardly applicable since they tend to be used to describe the interactions of more complex polities with their neighbors. But there is little question that conflict was one important aspect of the social lives of our ancestors. The question, then, is what are the characteristics of conflict in relatively simple human societies as well as those of our more distant ancestors?

Among our primate relatives, conflict between groups of individuals of the same species has been recorded but is rare. Perhaps the most common motivation for intergroup conflict is territorial defense, a pattern that becomes more common as people become increasingly sedentary and tied to particular pieces of terrain. This suggests that conflict intensifies significantly when we became more dependent upon domesticated plants and animals as the basis for our subsistence. Indeed, evidence for conflict between groups, such as trauma derived from conflict observed upon skeletal remains and the wholesale burning and destruction of whole villages, becomes more common after 6000 BCE, especially in the Middle Eastern and Mediterranean regions. After more complex societies are established at the end of this era, the term "warfare" is used more widely.

There are a number of times in the past when conflict may have been more intense or pervasive. One of the more interesting of these cases is the argument that Neanderthals were driven to extinction by our own species as it colonized Europe after 50,000 years ago. The evidence for this is slim, however, but it remains a distinct possibility since there is little of the Neanderthal genome to be found in our own.

Another episode of more intensive conflict that begins to resemble warfare can be seen in central and western Europe as farming populations began to move into lands traditionally used by hunting and gathering peoples after 6,000 years ago. These migrating farming peoples constructed what appear to be defensive structures around their villages, presumably to protect themselves from the indigenous inhabitants of the regions into which they moved.

Aside from these more dramatic episodes of conflict between groups, most conflict in our ancient past is within the social group or between small similarly scaled groups. In modern hunting and gathering societies, homicide is relatively common and is often sparked by sexual jealousies or rivalries. Some homicides, however, are directed at individuals who are habitually abusive to their neighbors and who make

demands on people that are unreasonable. Homicides over possessions are very rare.

Our evolution, however, is not just about competition and conflict. Cooperation is a powerful social force that apparently emerged fairly early in the evolution of our species. We see evidence of cooperation among chimpanzees when males group together to hunt small mammals. Sharing food, especially meat, between families is a form of cooperation that is common in almost all hunting and gathering societies. If people can be convinced that cooperation is in their best interest, such behavior may produce greater social solidarity in the face of challenges from rivals. Religion may well be a powerful force that motivates and sanctions cooperation, thus creating group solidarity.

—Mark Aldenderfer

■ Introduction: Conflict and Cooperation in Primate Societies

The primate order has had many members over its 50 million-year history, most of which are now extinct. Humans (*Homo sapiens sapiens*) are the only bipedal species left, as the other bipedal genus, *Australopithecus*, went extinct from the plains of East Africa over one million years ago. Nevertheless, scientists believe that studies of primate societies past and present can inform us on current human society, especially on the “nature versus nurture” debate concerning the origins and nature of conflict and cooperation in humans. Do we have a built-in genetic disposition to fight as well as cooperate for survival on a group level, or are these learned behaviors? Researchers now believe that a combination of the two may be at work.

Two classifications are currently in use as suborders for primates past and present. One classification uses temporal origins and evolutionary development to create the older suborder *Prosimii* (treeshrews, lemurs, lorises, and tarsiers) and the more recently evolved *Anthropoidea* (apes and humans). The other classification utilizes physical characteristics such as the presence or absence of a nasal rhinarium to create the suborders *Strepsirhini* (with nasal rhinarium) and *Haplorhini*. The former classification is more useful for looking at primate societies that are similar to human societies and will be used here.

The primate closest to humans was the *Australopithecine* genus, of which the famous “Lucy” was a member. They existed between four million and one million years ago in the same East African savanna that spawned the human genus. Fossil evidence suggests that both moved in cooperative groups and that both experienced interspecies and intraspecies conflicts. Scavenging and gathering activities may have promoted cooperation, while each group also experienced interspecies conflicts with other big-game predators from the feline and canine families. However, only the *Homo* genus made and used tools and was bipedally more efficient. Physical anthropologists cannot be sure if one group genetically or culturally influenced the other due to the limited evidence.

The modern primates closest to human society are the chimpanzees (*Pan paniscus*). The greater ape societies such as gorillas, orangutans, and gibbons have all been heavily impacted by human intrusions, but researchers still feel that chimp societies can inform us about human societies. Chimps are known to use simple tools, form territorial groups, engage in group hunts of monkeys, fight over mating rights, and even engage in group conflict over resource access. The family units of females and young are also similar to human units, as is the

need to protect and nurture highly vulnerable young. Perhaps most telling in chimp societies are the age sets and age grades, which roughly parallel those found in human societies. However, researchers are still uncertain if chimps developed conflict and cooperation in societies based on nature or on nurture. This mirrors the debate in human society research and explains why some researchers now turn to a mixed hypothesis, with both environment and genetics as variables associated with social conflict and cooperation.

Primate social studies may be compromised due to human impact on modern primates and the limited nature of the evidence from species that split from the primate order millions of years ago. Furthermore, humans as a species have been developing social conflict and cooperation mechanisms for perhaps one million years. The debate concerning “nature versus nurture” as the cause of cooperation and conflict in primates continues, with the “nature” proponents holding to a more ancient and genetic cause, while the “nurture” proponents hold to more recent and learned behaviors that can be modified. Those who sit in the middle on the debate see primate societies adapting to changing environments, using both biological and learned traits.

Territory Formation and Defensive Behaviors among Our Closest Primate Relatives

If for nothing else, humans are well known for their capacity for violence and hostility against their enemies. The origins of this tendency are much debated. Some have argued that humans have an evolutionary predisposition to violent behavior, while others claim that violence is not part of our evolutionary heritage but instead is

learned behavior associated with social, cultural, and political challenges.

To resolve these questions, or at least to seek evidence that could be used to evaluate these competing hypotheses, physical anthropologists and archaeologists have turned to the study of our closest primate relatives to determine if there is anything relevant in their behavior that may shed light on the human past. Once again, we are using data from our primate relatives as analogies and not as explanations.

Chimpanzees (*Pan troglodytes*) and bonobos (*Pan paniscus*) are our closest primate relatives based upon comparative studies of DNA. Chimpanzees have clear feeding territories that are aggressively defended by groups of adult males. These males patrol the edges of their territories in search of intruders and in some instances may actually enter the territories of their neighbors in a deliberate effort to kill members of that group, especially males. These encounters have been observed in the wild, so it does not seem that this aggressive behavior is the result of captivity. Such violence is strongly conditioned by the number of males in the group. All things being equal, larger numbers of males within a group will lead to increased violence against their neighbors.

Explanations for this behavior vary but appear to be related to the social structure of chimpanzee groups, which is strongly male dominated and in which males born in a territory never leave it over the course of their lives. Territories can be relatively large, but chimpanzees are able to move through them rapidly. Aggressive behavior is not clearly tied to resource abundance, although it may become a factor in times of extreme scarcity.

In contrast, bonobos, while having loosely defined territories, do not display these aggressive behaviors. Although there may be aggressive displays between individuals, even this is relatively rare, and male-dominated coalitions are unknown. Unlike chimpanzees, females in bonobo groups have enhanced status and often form coalitions of their own. In great part, this reduces violent behaviors both within and between neighboring groups. Males often derive their status from their affiliation with these coalitions, and this tends to reduce conflict between groups as well.

Gorillas (*Gorilla gorilla*) tend to live in groups composed of a single dominant male, multiple females, and their offspring. Gorilla home ranges are relatively small, and thus group encounters are not common. Gorillas show none of the aggressive behaviors so commonly observed in chimpanzees. Single roaming males, intent on finding mating opportunities, may engage in challenges to the dominant males of the groups they encounter, but this is not about territory per se.

Orangutans (*Pongo* spp.) have what might be best described as a semisolitary social organization. Fully adult males have large home ranges within which they move frequently, and within these ranges are a number of adult females and their offspring with whom the males maintain mating opportunities. These home ranges are defended against solitary males when encountered. However, adult male orangutans do not develop multimale coalitions and live mostly solitary lives. Active boundary defense and patrolling are unknown. Adult female orangutans often form small groups with other females and

their offspring. Since these territories overlap, there are occasions of hostile displays between females, although it is equally likely that relationships will be either neutral or affable.

Among the great apes, chimpanzees and humans are the most similar in their territorial behaviors. However, this should not be taken to imply that they are the best model or indeed the only model of what some of our hominid ancestors may have been like in remote antiquity. Of interest, however, is that in two of the species—bonobos and orangutans—female coalitions are important and serve, at least in part, to dampen male aggression against other individuals or groups.

■ Introduction: Conflict and Aggression in Early Human Societies

Evidence of warfare in early human societies can be found in archaeological materials that show indications of violent death prior to the development of agriculture and settled societies. Moreover, sociobiological theories utilized by some anthropologists suggest that early human behavior can be studied by analyzing primate social behaviors. However, there is disagreement as to how such behaviors developed, especially by anthropologists opposed to sociobiological notions. However, many anthropologists do agree that it is very likely that violence and aggression existed between groups of hunter-gatherers since the Paleolithic. Some speculate that humans possessed aggressive tendencies and had the behavioral potential for warfare long before the development of seden-

tary societies. Since hunting was a crucial element for survival, it followed that aggression was a means to this end. Thereby, warfare and conflict between groups of early humans were mostly over access to resources, using techniques and tools used for hunting.

While sociobiological theories that purport that early humans, much like their primate relatives (such as the modern chimpanzee), might have developed aggressive behaviors (aggression defined as the use of violence and the incidence of warfare), there are scholars who find such theories controversial. Scholars who subscribe to sociobiological explanations for violence and conflict in early human societies, such as anthropologist André Leroi-Gourhan, argue that biological drives predetermine human behavior.

Though initially displaying such behaviors when hunting game and developing tools for such activities, hunter-gatherers eventually used their developing aggressive tendencies against each other over access to resources. In contrast, French anthropologist Pierre Clastres argues that humans developed aggressive tendencies not as a result of innate biological drives but rather as a result of acquired behaviors established over time. Moreover, aggression in hunting does not translate directly into aggression for the purpose of violence and warfare against other humans in his interpretation. According to Clastres, early warfare was not directly linked to hunting but instead was derived from cultural contexts that made it necessary for survival of the group. However, regardless of these scholarly debates surrounding early human aggression, archaeological evidence sustains that violence did exist among hunter-gatherer societies.

Economic considerations are also part of the theories purported by anthropologists who study aggression in prehistoric human societies. Some scholars have speculated that hunter-gatherer societies, perhaps because of access to scarce resources, might have developed aggressive behavior amid the seizure of goods and land between groups in attempts to subsist off the land. However, new research has shown that resources were plentiful to many early hunter-gatherer societies, thus rendering this explanation more implausible and not really explaining how aggression and violence developed. While the evidence, in the form of human fossil remains, typically fractured skulls with signs of damage inflicted by weapons, illustrates incidences of violence, the economic considerations do not provide a full picture of such developments.

Anthropologist Lawrence H. Keeley compares early human societies with ethnographic studies that exist in today's world as a means to establish the origins of warfare. Studies of various stateless groups in contemporary Papua New Guinea and Latin America offer anthropologists like Keeley a glimpse into what hunter-gatherer warfare might have been like. Prevalent and ritualistic warfare as a means of ensuring access to resources and territory between modern stateless groups indicates that such behavior patterns

were perhaps adapted by early human societies as a means of ensuring subsistence and power over a region. Developments in the Upper Paleolithic illustrate that warfare did exist between hunter-gatherer groups akin to the aggression and conflict that characterizes the behavior of modern-day stateless ethnic groups. Therefore, the prior assumption by archaeologists that "civilization," which was characterized by settled agricultural societies and increasing complexity, was a prerequisite to warfare and aggression is no longer an element of scholarly consensus on the subject of early human violence.

By the time of the development of agriculture, human societies had already acquired the necessary implements for organized violence and warfare. However, the establishment of cities and settled communities, particularly in the Near East, created a further layer of complexity to the organization of violence under the auspices of the state. In the early Neolithic, growing population densities due to the widespread development of sedentary agriculture and the resultant competition over resources, particularly scarce agricultural lands, led to contentious situations among emergent villages and cities. The incidence of organized state violence emerged during this period as a result of this endemic warfare as successful war leaders took the helm of political power at the village and city levels. Much like early hunter-gatherer warfare, sedentary societies found warfare necessary for the protection of their resource base and for territorial expansion at the expense of another group.

Conflict and Cooperation among Our Earliest Ancestors

Primates are one of the few animal orders where living in social groups is common; our earliest apelike ancestors are no exception. Living in large social groups evolved and has been maintained throughout a large number of primate lineages, mainly through survival advantages resulting from predation pressure. Associated with group living comes a necessity to cooperate with other group members as a means to ensure inclusion in the social group. Conflict as a result of competition for access to resources and mates is also a feature of group living, both within and between groups.

The human and chimpanzee lineages split approximately six million to eight million years ago. Much of what is known of the social behavior of our bipedal hominin ancestors since this divergence has been obtained from the paleontological and archaeological record, specifically through the application of knowledge about living species to the study of this prehistoric evidence. The study of living great apes shows that the degree of size difference between males and females is linked to the level of male-male competition within a species; species in which males monopolize access to females through intense competitive encounters, as observed in gorillas, have higher levels of body size dimorphism compared to those who adopt pair-bonded or multi-male/multifemale mating systems. Canine size is also an important indicator of social behavior; large canine size in primate males is associated with threat displays and low tolerance for one another.

Evidence from the Pliocene fossil record between 4 million and 2.3 million years ago shows that *Australopithecus afarensis* and *Australopithecus africanus* demonstrated moderate to high levels of body size dimorphism. This is broadly indicative of social structures in which

high levels of male-male conflict are apparent. However, these early hominins also demonstrated derived characteristics of reduced canines, indicative of higher levels of tolerance and cooperation and lower frequencies of aggression. The first archaeological evidence for cooperation in our earliest ancestors is attributed to *Homo habilis* approximately 2.5 million years ago. These early members of the genus *Homo* are thought to have been responsible for the first stone tool kit, known as Olduvan technology. Given the widespread transmission of this technology, which persisted for over 800,000 years, a high level of cooperation among these early toolmakers was likely.

There is clear evidence of conflict and cooperative behavior in our hominin ancestors throughout the Pleistocene. Cranial specimens of both *Homo erectus* (who lived between 1.7 million and 500,000 years ago) and *Homo neanderthalensis* (who lived between 500,000 and 30,000 years ago) have been discovered that exhibit healed skull fractures, inferred to have been the result of purposeful blows to the head. Along with such evidence of interpersonal violence, cooperation among individuals has become more and more prevalent, and this has been coupled with an increasing brain size through the evolution of *Homo erectus*. It has been argued that a large brain in the *Homo* lineage has evolved, partially as a result of increased cognitive demands required to deal with larger social networks. In conjunction with inferred increase in social group size came advances in lithic technology, with the appearance of more sophisticated Acheulean tools approximately 1.6 million years ago. As a result of increased consumption of meat from this point onward, a shift in subsistence strategies emerged from the scavenging of meat to cooperative hunting of larger-bodied prey.

Toward the end of the Pleistocene just two species remained: anatomically modern humans and Neanderthals, both of whom demonstrated large relative brain sizes, complex social groups, and associated cooperative behaviors. Modern-day hunter-gatherer groups are thought to represent the ancestral behavior of both modern humans and Neanderthals in which food sharing behavior and intergroup aggression are common. Around 35,000 years ago, anatomically

modern humans, adapted to hot climates, began to inhabit eastern Europe, an area traditionally occupied by cold-adapted Neanderthals. Armed with a more extensive tool kit and cohesive group structure, modern humans would have been able to outcompete Neanderthals, this being a leading hypothesis for their demise. This highlights the importance of both conflict and cooperation to the success of our modern human ancestors.

The Archaeology of Aggression and Violence in Early Human Societies

The meaning of the concept "violence" in terms of acting violently against other people is culturally coded. In many societies of the world, physical violence is considered a violation of human rights. In this context, the killing of one human being by another is perceived as a violent act. This connotation, however, is lacking in the context of some societies where we find exceptions in the attitude toward violence.

One such case is Iban society in Kalimantan (Borneo). A prominent feature of historical tradition among the Iban (or Sea Dayak) is head-hunting, and this includes the cutting off of an adversary's head while the person is asleep. The head was kept as a trophy, ensuring the transfer of the adversary's energy into the keeper of the head. As such, head-cutting is not considered abominable by Iban people but rather is a ritual act.

THE BURIALS AT SHANIDAR CAVE (TURKEY)

Shanidar Cave, located in the Zagros Mountains of northern Iraq, was excavated in the 1950s. Several adult and young Neanderthal skeletons, dating between 60,000 and 45,000 years ago, were discovered along with Mousterian artifacts. These skeletons are especially interesting for a number of reasons.

First, several skeletons show recovery from bone trauma, which suggests that Neanderthal life was harsh and difficult. This also insinuates that disabled individuals were cared for by the group. The Shanidar 1 skeleton, for example, had severe arthritis in his feet and a healed fracture on his left eye orbit, which may have caused blindness. Moreover, his right side was either paralyzed by the blow to his eye or he was born with his right arm, shoulder blade, and collarbone not fully developed. In either case, he compensated for this by using his teeth for grasping and holding objects, attested by the severe wear of his upper incisors. When Shanidar 3 was killed by a rock fall in the cave, he was recovering from a projectile point found embedded in his ribcage.

Second, although most of the Shanidar Neanderthals were killed by rock falls from the cave roof, some were intentionally buried. Flower pollen found in the graves suggested that ritualistic activities for the dead were carried out, but this was later discounted based on the context of the pollen grains. The burial of their dead and prolonged survival of the infirm suggest that the Neanderthals from Shanidar Cave had behavior similar to modern humans.

► VIOLENCE AND CONFLICT IN AUSTRALIAN ABORIGINAL ART

Australian Aboriginal art in the form of rock art, bark paintings, and carvings provides one of the oldest continuous documentations of violence and conflict from the Stone Age to modern times. In the 1830s Australia was being colonized mainly by Europeans, who encountered over 600 “tribal” groups speaking over 200 languages in four main groupings with many social and cultural traditions. Conflict between Europeans and Aboriginals is well marked in the rock art from the 1880s on, with Europeans and guns often the leading theme. Based on art that depicts small group violence along territorial borders, in precontact times Aboriginals engaged in raiding and feuding over territory and breeding issues. Evidence includes depictions of long war spears, spearthrowers, and war boomerangs along with territory markers. This record extends tens of thousands of years back in time. Based on more recent ethnographic records, much of the violence and conflict was mediated by rituals between “tribal” groups and is similar to conflict resolution rituals found throughout Stone Age civilizations. The coming of Europeans with guns, ships, and diseases in the nineteenth century ended this age-old system of equilibrium, resulting in increased violence not only along European-Aboriginal borders but also within the Aboriginal core areas.

Given the arbitrary, culturally specific connotation of the term “violence” in the world’s cultures, a modern observer is cautioned not to apply Euro-American conceptualizations and value systems in a generalizing way to the world of early human societies. The archaeological record may produce evidence for physical violence

in various forms (e.g., skulls fractured by weapons, heads of arrows or spears stuck in skeletons, the body of a strangled person retrieved from a bog), but the context of such finds may point to acts of ritual killing.

As a collective form, violence may be practiced on a gradually increasing scale, from violent clashes between clans or kin groups to tribal wars. In complex societies, certain radical forms of collective violence have developed, among them “ethnic cleansing” that may assume the magnitude of genocide. Ethnic cleansing has been practiced by many “civilized” people, from the times of the Assyrian and Hittite empires to the genocide crimes committed by Nazi totalitarianism and beyond (e.g., the clashes of the warring factions in the Balkans or between the Tutsi and Hutu in central Africa in the 1990s).

Large-scale violence cannot be assumed for preagrarian societies since the size of local populations was fairly restricted. In addition, the command structure as a precondition for the direction of collective violence to a target group was still weakly developed in early human communities. The argument of intertribal violent clashes over issues relating to authority and the usurpation of political power, brought forward by Pierre Clastres in the 1970s, was based on observations about territorial disputes among recent traditional cultures in South America. The transposition of the relevance of such an agenda to prehistoric societies is problematic, since an awareness of territorial separation with a conflict-producing political impact cannot be verified for prehistoric and stateless communities.

As for the Upper Paleolithic era and its European context, there must have been lively and peaceful interaction among different local groups of hunter-gatherers. Otherwise, it would be impossible to explain the high degree of cultural uniformity that is typical of the Gravettian period between circa 27,000 and circa 19,000 BCE. The zone of cultural convergence stretched along the southern fringe of the contemporary ice shield, from southern France to the Ural Mountains in Russia. Among the diagnostic terms of this uniformity is a remarkable similarity in habitation structures, in stone-tool tech-

nology, and in forms and styles of artistic representation (i.e., figurines).

There has been speculation that the spread of agriculture from western Asia into Europe would have been a movement of warlike agriculturalists who worshipped a bull god and intruded into areas of hunter-gatherers, destroying their camps and driving the local population away, in similar ways to white settlers in North America who claimed possession of their land in clashes with the Indians. For the initial period of the spread of agriculture in southeastern Europe (i.e., sometime before 7000 BCE) there is no proof for the intrusion of aggressive Neolithic migrants from Anatolia or for an independent bull cult. The bull appears much later in religious iconography and is best known as an attribute of the Mesopotamian goddess Ishtar.

In all probability, the spread of agriculture in the Neolithic was no violent process but instead unfolded in a peaceful way. A typical indicator of violent clashes is layers of ash (of burnt houses) in the stratigraphy of settlements. It is significant that this indicator is missing from the archaeological record of most Neolithic settlements in western Asia and southeastern Europe. It has been concluded that the adoption of the Neolithic package—in terms of the technology of plant production and lifeways associated with it—enhanced something of a nonviolent “Neolithic spirit.”

And yet, there are exceptions to this general view. At some places—Talheim (Germany) and Schletz (Austria)—mass graves have been unearthed with skeletons bearing traces of violent killings. These ancient settlements were occupied by Bandkeramik agriculturalists in the sixth millennium BCE. There has been speculation about the reasons for the considerable amount of violence. With respect to Talheim, it has been conjectured by Chris Scarre that its inhabitants had been killed by raiders from a neighboring Bandkeramik settlement, though whether as part of a feud or simply to steal livestock or food stores cannot be determined.

Forager/food-producer relations in prehistoric Africa are described in three alternative models, none of which associates violent clashes. Foragers are assumed to have maintained their own economy while retaining connections with farmers, to have exchanged commodities and ideas with food producers and to have imitated sedentary people’s lifeways, and to have engaged in coresidency and intermarriage with farmers. The latter option is well documented for northern Europe in the second millennium.

What produced a considerable amount of violence in early human societies was the confrontation between differing socioeconomic systems and related worldviews, particularly of pastoralists and agriculturalists over the control of land that could be used both for plant cultivation and as pastures for animals. Scenarios of major clashes have been reconstructed from the archaeological record for eastern Ukraine in the fifth millennium BCE, when nomads from the Eurasian steppe zone extended their socioeconomic space farther west. Their thrust resulted in violent incursions into the area with agrarian settlements. Evidence for this large-scale conflict is a dramatic increase in the number of arrowheads found inside and around settlements and ash layers. A new item of material culture was introduced by the people from the steppe: horse-headed scepters or maceheads.

■ Introduction: Conflict in Ancient Village Societies

In ancient villages where Stone Age hunter-gatherers first settled down in the Neolithic period at the end of the last Ice Age, conflict was transformed by population growth associated with permanent landscapes. Surprisingly, early villages around the globe were relatively peaceful compared to their Paleolithic forbearers and later urbanized state descendants. Conflict was initially associated with individuals and small related groups concerning village access, revenge, and reproduction issues. Conflict often led to violence and also to the development of conflict resolution rituals to mediate the violence. Most early villages in world history were initially formed around the models of power sharing associated with their nomadic ancestral bands. However, as populations grew with year-round mating and resource access, new adaptations became necessary. Growing villages came into resource conflict with other growing villages and with their still nomadic neighbors. This resulted in social stratification and organized conflict.

Evidence for ancient village society is mainly the realm of anthropologists and archaeologists, as few written records exist from prehistory when early villages formed in the Neolithic period. Cultural materials from landscape and tools to human remains and rock art are used to reconstruct the prehistoric past. Social scientists in these fields rely upon archaeological data and dating methods to examine conflict in ancient villages. Anthropologists studying more recent small-scale village societies create ethnographies or written descriptions of these cultures. Conflict studies from these ethnographies are used to develop analogies and correlates for ancient village society. Social scientists have long noted the correlation among population size, segmented or complex societies, and levels of individual and group violence or conflict. Small-scale societies of families and bands, whether nomadic hunter-gatherers or herders or sedentary farmers and fishers, tend to have conflict at the individual or family level. Conflict is as likely to be within a family as between families or bands. Conflict mediation in the form of sociocultural ritual for controlling conflict behavior is

usually well developed for both individual behavior and kin-related behavior. Perhaps the individual was so valuable in small-scale societies that only those societies that mediate conflict behavior would survive, while others are effectively destroyed by the loss of too many productive members. Whatever the case, such a model requires small populations with relatively abundant natural resources.

Conflict in village society ethnographies is not uncommon, as is evidenced by the presence of conflict mediation rituals and by numerous episodes of violence in the ethnographic record. Conflict in the form of individual and family or band violence toward another member of that same group is most common. Issues that lead to conflict generally involve prime-age males initially but may later include females and other small group members. Clashes over reproduction access to females, treatment of marriage partners and children, and access to natural resources were the most common cases. In terms of conflict between groups, revenge killings, raids, and line battles are also quite common in the ethnographic literature. Leaders with fraternal groups in segmented societies were very often involved. However, to extrapolate these findings from more modern village societies back into the ancient and often ambiguous archaeological record is difficult.

One finding from the ethnographic record, however, does seem to have correlates in the archaeological record of ancient village societies. The presence of segmented societies in both records is an indicator of increased levels of group conflict. Segmented societies generally result from population growth that leads to increased social complexity needs for the group to survive and thrive. The general pattern in the archaeological record for the emergence of complex, segmented societies is clear when a developmental adaptation model is used. Thus, to examine the role of conflict in early village societies in world history, scholars need to use both a spatial and a temporal analysis.

In the Paleolithic period just before villages emerged, archaeological data indicates that most

hunting bands practiced conflict and violence within their bands and toward other groups. Individual skeletons with violent causes of death are a good sign that conflict manifested as violence impacted individuals, while group remains with violent death signs are indicative of inter-group conflict. Both indicate that conflict resolution mechanisms were necessary and often failed in the Paleolithic world of hunter-gatherers. The cemetery in Nubia known as site 117 or Jebel Sahaba when excavated in 1964 by archaeologist Fred Wendorf yielded human remains radiocarbon dated to 13,700 years ago (11,700 BCE). Fifty-nine humans were recovered, including at least 40 percent who died in violence due to conflict. Cause of death was most commonly from multiple projectile points, including bow and arrow or spear. In some cases more than a dozen wounds are noted per individual, making it unlikely that these were human sacrifices. Roughly equal numbers of men, women, and children were killed and in roughly equal percentages, though most of the men were buried individually, perhaps having been killed away from the site. Such conflict and violence took place within the context of Late Ice Age hunter-gatherers clustering around dwindling or changing resource bases due in part to a drying climate trend. Wild animal and plant species changed, and coastlines and secure locations of water also changed, with the result that Paleolithic hunter-gatherer bands had to adapt to ensure survival. These bands began a process called “cyclical nucleation,” or seasonal settlements around these resources. Some animals and plants were transported with these bands, and horticulture became more common. Small hunter-gatherer bands settled down perhaps around decreasing water and food supplies and staked a permanent claim to that area.

This process of the “emergent village” can be seen at early village sites at Paloma in Peru (5500–3000 BCE), the Oaxaca Valley in Mexico (4000–3000 BCE), Mehargarh in India (6500–6000 BCE), Early Jomon culture sites in Japan (5000–2500 BCE), Yangshao villages in northern China (6000–5000 BCE), ancient Near Eastern villages such as Çatalhöyük (7500–5700 BCE), Jericho (9000–6800 BCE), and many Natufian villages in Egypt and the Levant (ca. 10,000 BCE).

The intermixing of village and nomad hunter-gatherers increased. Some villages grew in population and complexity, while others failed. The successful villages used more local resources than surrounding villages and nomads, both on an individual or per capita scale and as an overall group, especially when year-round occupation and usage are taken into account. Urbanism emerged as a by-product.

The confusion for researchers of conflict comes at the next stage. As certain villages reached populations where social segmentation and stratification result, larger group conflict became evident. However, it is not clear if this is created by surpluses within the village, as some researchers theorize when villages become towns and cities, and urbanism leads to surplus and the ability or affordability to go into organized conflict with others. Another theory has villages competing over scarce resources, and thus it is lack of surplus that creates tensions leading to organized conflict. Yet another theory sees the conflict as motivated by the emergence of elite village social members who use conflict to gain, maintain, and legitimize their social standing. A final idea concerns the role of still-extant nomads who, pushed to the edges of natural resource areas by growing villages, begin to prey upon those villages using their nomadic hunting skills applied to humans as their advantage.

Several points emerge concerning conflict data from these Neolithic sites. Little direct evidence of group conflict is seen in these early unsegmented village societies. Few sites were fortified, cemeteries have little evidence of violent death, and few tools were developed specifically for conflict. Populations increased as year-round mating took place versus the seasonal mating patterns of nomads. Wild plants, animals, and natural water sources were often exhausted by the increased populations before large-scale domestication and irrigation took place. Pottery, grinding stones, storage pits, and pit houses, all signs of permanent populations, often emerged only well after settlements formed. In some cases, villages were seasonally utilized before becoming permanently occupied. Other bands of people continued to practice nomadic lifestyles around these early villages, increasing interaction, cooperation, and conflict potential.

Based on archaeological and ethnographic data, ancient early village societies around the world experienced an unusual lull in conflict, at least as manifested in the record of discernable violent death evident in skeletal remains. The earlier Paleolithic and later historical phases of urbanism and first states both have increased levels of conflict manifested as violence when compared to early village societies. Conflict and cooperation within smaller, more nomadic groups was transformed to meet the adaptation needs of later larger village groups. This could be due to differential successes of conflict mediation, undetectable forms of conflict in early village society, the unique requirements of village and agriculture life, or something else as yet unstudied by researchers.

Warfare and Conflict in Ancient Village Societies

Social conflict can range from individual strife within a society to organized, armed conflict between societies, or war. In all cases violence is usually evident in the historical and archaeological records. However, the relationship between conflict, violence, and warfare has remained an area of great debate in the scholarly community. What is the nature of conflict and war in humans? Is it natural and biological, learned and environmentally driven, or perhaps a combination? When is evidence of violence in the archaeological record a murder, execution, part of a feud or raid, or a result of full blown war? Does war have an origin point (or points) or has it al-

ways been a part of the human record? The best database available for examining such questions comes from the Ancient Near East, especially from Mesopotamia, Egypt, and the Levant, where a rich archaeological record exists from the Paleolithic and Neolithic periods concerning emergent villages and social conflict. Since writing and leadership are associated with state level war and leadership, they will be avoided here.

During the Paleolithic, most humans practiced a nomadic, hunter-gatherer lifestyle that kept human societies at the family and band levels as they moved to and with the resources. Cave paintings and skeletal remains indicate that conflict in the form of violent death was not uncommon as groups encountered each other. However, since most of the past evidence did not survive, the context of the violence is difficult to determine. The nine thousand-year-old Kennewick Man from Northwest North America is a classic example. He had a healed wound from an embedded spear point but without further context and evidence it is not possible to determine the nature of the social strife that caused the point to become lodged in the pelvis. Much of the Paleolithic evidence for conflict is of this nature but not all of it.

Some researchers believe that even war can be identified in the record from the period before humans settled into permanent villages. Two arguments are made. First, little evidence of the past remains so if consistent evidence of social conflict is found, the actual case numbers must have been far greater in the Paleolithic period. The second argument centers on the archaeological site of Jebel Sahaba or site 117, a rare, Paleolithic cemetery in Nubia excavated in 1964 by archaeologist Fred Wendorf. Over one hundred human remains were eventually recovered and radiocarbon dated to 13,700 years ago (11,700 BCE). At least 40 percent died of violent conflict wounds. The most common cause of death was from multiple projectile points such as arrow or spear points. Some individuals had more than a dozen wounds. Roughly equal percentages of men, women, and children were killed though most of the men were killed offsite and buried later in the cemetery. Certainly the highly skilled hunters of this period were capable of such violence from a technological stand-

point as bows, spears, and clubs were already in use. Was it evidence of armed, group conflict? The debate has continued on how to interpret the evidence at Jebel Sahaba but those who see war as developing before settled villages emerged cite it as strong evidence to support their theory of war having always been with humans.

In the Neolithic, as humans settled down, early villages around the world do not have much direct evidence of group conflict. Cooperation may have been premium at the time or mortuary practices may have changed. This peaceful phase apparently did not last based on evidence from the Ancient Near East. Population growth and social conflict emerged only a few centuries after village settlements began to grow. The archaeological site of Jericho (Tell el-Sultan) in the Levant indicates Natufian bands of hunter-gatherers settled around the permanent spring onsite in a few huts and a shrine. Population increases by the eighth millennium BCE led to a village of several thousand people and fortifications soon emerged. A 13.12 by 9.84 foot (4 by 3 meter) stone wall was surrounded by a 26.25 foot (8 meter) wide rock cut moat, and a 26.25 foot (8 meter) tall tower capped the works. Arguments that these constructions served as water works have not fared well, but the village did, surviving for several thousand years among a dozen other regional villages.

Jericho's fortifications were rebuilt several times and it was not the only fortified site in the region. Similar walls were excavated at the Beidha site as well. Fortifications and the implied social conflict were not yet widespread but that would change dramatically by the end of the Neolithic in the Ancient Near East. Fortifications (walls, moats, towers), changes in weaponry (metals, slings, bows, daggers, javelins, maces), and signs of violent ends to villages and societies (burning of villages, violent deaths) all indicate growing conflict in the late Neolithic villages of the regions. Some of this was internal social conflict, some of it undoubtedly warlike in nature.

A drying climate and human ecological impacts via growing populations likely led to social conflict between villages, and between villages and nomadic bands. Eight-thousand-year-old Tel es-Sawwan near Samarra had massive walls and a 9.84 foot (3 meter) wide moat built. At Anshan

(Tel Malyan) near Shiraz, Iran, around 3500 BCE, a massive, concentric set of walls over 3 miles (5 kilometers) long surrounded over 494 acres (two hundred hectares) of land. Built with a stone foundation, mud-plastered glaucis, and brick topped, the innermost of the three walls was 16.4 feet (5 meters) thick. Anshan was an early center of copper metallurgy as was the fifth millennium BCE Susa where fifty-five copper axes were buried in elite burials. The earliest known copper spearheads and masses of clay sling balls are from this time as well. Villages such as Susa, Uruk, and Ur might number a few thousand inhabitants in the Neolithic but grew to ten times that by the Chalcolithic (metals age). Settled village societies consisted of blended cultures that emerged as proto-Sumerian civilization. By 4000 BCE most researchers believe Sumerian polities had fully formed warfare replete with military systems including fortifications, logistics, armies, special weapons and armor production, and specialized military units such as infantry and heavy chariots with command and control by specialized leadership.

In Egypt, unlike Mesopotamia, villages developed in environmental isolation along the Nile River as it flowed through the Sahara Desert. This promoted a linear rather than circular geographical development of village society and conflict. Natufian bands also settled in villages here, but the water supply on the river and delta was much more stable than the flood prone Tigris and Euphrates rivers. Resources such as wood, copper, and gold were not found along the lower Nile and promoted international trade just as in Mesopotamia. By 5,000 years ago, Egypt unified politically a long but narrow strip of territory by using the Nile and social conflict. The early village and emergent chiefdom of Naqadda (6,000–4,000 years ago) was a trade center for metals and like Uruk in Mesopotamia may have been the center of early expansion attempts. From this time the Hierakopolis "painted tomb" and the Gebel-al-Araq knife handle both depict battle and kingly sacrifice scenes, including animal skin armor, daggers, a variety of Neolithic maces, javelins, and spears, and the use of boats in naval combat.

Egyptian use of both stone and copper weapons simultaneously indicates the difficulties of

labeling the past as Neolithic and Chalcolithic. Egyptian expansion into Libya, Nubia, the Sinai, and Canaan in predynastic times led to the development of fortifications in those regions, both by Egyptians and against Egyptian aggression. Massive fortifications were constructed at Ahad in southern Canaan as well as along the cataracts of the Nile River toward Nubia. By the time of legendary King Narmer (Menes), Egypt had been united from a series of river villages into dynastic kingdoms with armed coercive force an integral part of the process. First dynasty kings recorded their military exploits in writing just as early Sumerian priest-kings did.

Based on preservation levels and research breadth and depth, the Ancient Near East is the best area to examine the relationship between village social conflict and emergent warfare. In Mesopotamia, the success of some villages led to the development of fortifications perhaps to keep out nomad raiders and other rival villages. Successful long-term villages became towns often associated with urbanism, trade, metal production, and the use of coercive force, perhaps internally and externally. Warfare fully emerged by the Chalcolithic with metals as a key ingredient. In Egypt however, war and coercive force may have played an even larger role in unifying areas of the Nile. The idea of leadership, such as priest-kings in Mesopotamia, and politics and pharaohs in Egyptian dynastic kingdoms, appears tied to the use of coercive force and the development of social, stratified power. Furthermore, the role of villages as precursors to armed, organized groups in social conflict is evident in the Ancient Near Eastern record.

The Archaeology of Leadership and Conflict in Village Societies to 4000 BCE

Archaeology interprets the past through the context of cultural materials such as tools, architecture, and human remains. Little of the prehistoric past survives, and thus large gaps in prehistory exist. One gap is in the relationship between leadership and conflict in village societies before 6,000 years ago. Current evidence suggests that other leadership forms emerged before conflict leadership. Difficulties include identification and interpretation of conflict and leadership in the archaeological record. Social scientists agree that conflict emerges over resources, leadership ambitions, and cultural beliefs. However, the presence of these variables is hard to detect in the early villages that emerged around the world between the last Ice Age and 4000 BCE.

Evidence for conflict in prehistory is found in skeletal violence, weaponry, and fortifications. Neolithic skeletons have evidence of violence usually in the form of males killed with arrows and both males and females with cranial fractures, sometimes healed. This informs scholars only that male-oriented long-distance conflict using hunting weapons was most common, followed by close-range concussing-weapon conflict involving all members of a village. The role of conflict leadership, identified through differential burial practices, specialized architecture, and cultural materials is unknown. The problem is in understanding the relationship between conflict, evident throughout the Neolithic, and various forms of religious, political, and conflict leadership evidence, only discernable together in the later Neolithic. Generally, a segmented and hierarchical society is associated with leaders who have special duties and status within a society. For early villages, issues of ecology are associated with emergent leadership. Increasing populations permanently settled on a finite resource base needed better control of the environment, which came through specialization of skill sets including leadership in the village. Shamans from old nomadic groups that settled down would be likely candidates for leadership in an emerging village with their specialized

knowledge of plants, animals, celestial time-keeping methods, and the commandment of social respect. Political and commercial leaders also emerged with specialization and the need to create orderly villages and acquire unavailable local goods. However, conflict specialists were readily available from the old hunting nomad skill sets, and leadership was not needed initially to help form specialists in that area.

This process of the “emergent Neolithic village” is evident around the world at sites like Paloma and Caral in Peru, the Oaxaca Valley in Mexico, Linear Ceramic and Trypillian Culture sites in Europe, Lajuradewa, Jhusi, and Mehargarh in South Asia, Early Jomon sites in Japan, Pengtoushan, Peiligang, and Yangshao villages in China, Gobekli Tepe and Catal Huyuk in Turkey, and Jericho in the Levant. A model of emergent leadership can be posited based on the data from these and other early permanent settlements. Complexity with population growth led to year-round decision making and the need or want for year-round leadership, different from the older nomadic model of timely decisions made by family and band elders. Based on architecture and cultural material remains, three main leadership groups came to dominate Neolithic villages by 4000 BCE. These were political, religious, and military specialists.

Religious and political elites (presumably leaders) emerged by the Middle Neolithic based on the prevalence of religious and public architecture, differential burials, and specialized artifacts that suggest centralized leadership to construct, produce, distribute, and control. Conflict leadership evidence is not seen until the Late Neolithic; however, as is always the case in prehistory, absence of evidence is not necessarily evidence of absence. Conflicts might well take place outside of village areas in “battle-zones,” and coercive force might be used as a threat more than a reality to establish order in growing village populations. Jericho is the Early Neolithic exception, with a wall, moat, and tower. Gobekli Tepe in Turkey and Paloma in Peru are both examples of sites with religious and political architecture or artifacts but no evident conflict. Entire village cultures in parts of China, India, southeastern Europe, and Mesoamerica also have little evidence of military lead-

ership and conflict until the Late Neolithic. Some sites remain ambiguous concerning military specialists. Çatalhöyük in Turkey has burials and artifacts such as maces indicative of specialists, but its “pueblo” style of architecture has only identifiable religious and politically specialized rooms, and researchers still debate the site’s defensive characteristics.

In the Late Neolithic fortified sites with specialized weaponry became more common, hinting at the emergence of military leadership in terms of construction, production, command and distribution. Eight thousand-year-old Tel es-Sawwan near Samarra had massive walls and a moat 9.8 feet (3 meters) wide built. At Anshan (Tel Malyan) near Shiraz, Iran, 5,400–4,800 years ago a massive concentric set of walls over 3.1 miles (5 kilometers) long surrounded over 494 acres (200 hectares) of land. Elite burials at Anshan and Susa are associated with early copper metallurgy, but it is not clear if copper axes were ritually powerful or were for actual utilitarian use in conflict. Egypt too, at the village of Naqadda (6,000–4,000 years ago), shows this emerging relationship among metals, elites, and conflict. In Europe, Linear Ceramic culture sites were built with trenches and palisades. In the Oaxaca Valley of Mexico, villages formed up shortly after 6,000 years ago, and by 5,000 years ago growing populations had signs of segmentation, elites, and external conflict. Banpo, the type site for Yangshao culture in northern China had a moat 16.4 feet (5 meters) wide surrounding 9.8 acres (4 hectares) of villages by 4500 BCE.

Population density and environmental adaptations appear to be key variables in the development of identifiable leadership in the prehistoric archaeological record. The emergence of coercive force and conflict in association with leadership is one of the last associations manifest in the Neolithic period, not one of the first. The current state of research may indicate that religious leadership around shrine sites emerged first, followed by population growth and the need for political leadership to negotiate resource use and access. Only at the end of the Neolithic did military leadership begin to emerge on a par with religious and political leadership.

Thought and Religion

One of the distinguishing aspects of our species is the capacity for symbolic thought. Unlike other species, we have real self-awareness. Through the medium of language, we are capable of expressing thoughts and emotions in complex and novel ways. Language and other media allow us to imagine and create wholly new aspects of culture. Through this capacity, we are not bound by genetics or learned behavior. Although it is likely that some of our nearest primate relatives have some symbolic abilities, these have only been observed after extensive training and coaching in laboratory settings.

At what point in the evolution of our species did this remarkable capacity appear? It is best to recast this question to think about it as a process instead of as an event. There is no “cerebral frontier” that one of our ancestors crossed from a very limited symboling capacity to one that was more fully human. But it is the case that significant changes in the structure and capacity of the brain were required to create a symboling capacity.

One of the principal difficulties in the analysis of this process is the lack of clear material correlates of “thought” and symbolic capacity. In the deep past, we rely solely upon data obtained that reflect changes in the cranial anatomy of our ancestors to get some insight into how the brain was structured. Although the absolute size of the brain is important, more important is evidence about the structure of the brain itself. This is studied by examining endocasts, or physical models of brain shape made by filling fossil skulls with resins or other similar material. Endocasts may reveal new patterns of vein and artery placement, which may reflect a new importance of certain brain areas in response to adaptive pressures, or changes in certain structures known to control the capacity of abstract thought in our own species. Based on these criteria, it is likely that *Homo erectus* had achieved some capacity for symbolic thought.

As we move closer in time to the modern era, new lines of evidence can be used. One of the most important of these is that of artifacts used for personal ornamentation. Objects such as beads and pendants are thought to signal attention to personal difference. Chimpanzees, for example, while showing distinct personalities, make no effort to use objects to distinguish themselves from others. Humans, in contrast, use tattoos, paint, and other types of ornamentation to show both group and personal distinctions. These kinds of display are seen as evidence for self-awareness. Although pigments that could have been used as body painting are thought to be over 100,000 years old, such decorative objects appear in greater numbers after that date. It is possible, then,

that both *Homo erectus* and *Homo neanderthalensis* had this degree of self-awareness. But it is also clear that such behaviors were not widespread in these species.

For many scholars, the appearance of art—objects that have what appears to be a nonutilitarian function—is a clear signal of the capacity for symbolic thought. The earliest known expressions of art, broadly defined, appear in Africa, the Middle East, and Europe as early as 300,000 years ago and possibly much earlier. These finds include pigments, bones with regular incisions, and a crude but recognizable female figurine from Berekhat Ram on the Syrian-Israel border. The function of these objects is unknown.

Despite these discoveries, most of what we know as art in antiquity is seen in greater frequency after 50,000 years ago. Many utilitarian objects dating to this period have decorative treatments and flourishes that speak to an artistic aesthetic, and some objects, such as the famous “Venus” figurines, have no obvious utilitarian function, nor does the famous cave art from sites such as Lascaux or Altamira. How, then, can they be interpreted?

By far, the most common explanation for the appearance of cave art, figurines, and other similar objects is that they served some sort of religious role for the peoples who produced them. Religion, as a category, is a Western construct. That is, many peoples today who live in small village-based societies have no term in their languages for our word “religion.” However, all societies have classes of entities that can be broadly defined as “spirits,” or nonhuman actors, that populate this world. The term “animism” is often used to describe this set of beliefs. In some societies, the dead become spirits who become entities of veneration. In many modern hunting and gathering societies, there are people known as shamans who are said to be able to communicate with spirits. These shamans perform healing rituals and in some societies protect their groups from spiritual attacks sent by shamans of competing groups.

The origins of religion are hotly debated, and archaeology has been drawn into the discussion. Unfortunately, direct evidence for anything that can be clearly labeled as “religious” activity in the archaeological record is difficult to come by. Perhaps the earliest expression of religion is the intentional burial of the dead by Neanderthals at a number of European and Middle Eastern sites. Whether this is religion or some other social practice cannot be inferred, however, with any degree of certainty. Similarly, the interpretation of cave art as an expression of religion, while a distinct possibility, cannot be directly demonstrated.

Activity that is more likely religious in nature becomes more commonplace with the advent of sedentary life. At numerous early village sites in the Middle East, rooms of some structures appear to have been used as shrines, and at others, such as Göbekli Tepe in modern Turkey, monumental architecture inscribed with images of animals common in the region was erected. Lacking habitation features, the site is thought to have served a religious function for the people who built it.

Humans, in contrast, use tattoos, paint, and other types of ornamentation to show both group and personal distinctions. These kinds of display are seen as evidence for self-awareness.

One of the new occupational specialties that emerges with sedentary life is the full-time religious specialist. By the end of the era, it is likely that there are people who take on the role of what we today would call a “priest.” Although we have no knowledge of the meaning of the religion practiced at that time, we find evidence of more elaborate religious structures and a wider range of artifacts that appear to serve religious purposes.

The contributions to this theme explore these and other topics in detail, and together they illustrate the evolution of the human mind and describe the ways in which this evolution created social and religious institutions that continue to be important in modern times.

—Mark Aldenderfer

■ Introduction: The Evolution of Human Language

Most mammals, birds, and reptiles rely to varying degrees on vocal or at least audible communication, and in this regard humans are no different. Primates, including humans, are highly communicative mammals, using not just oral cues but also gestures, or body language, to communicate emotions and threats. Some monkeys link calls to specific types of dangers and predators. Chimpanzees contort their faces to represent emotions like fear and aggression. Humans, however, have taken both vocal-lingual abilities and symbolic communication to the extreme.

Human speech itself is much more complex than the vocal repertoire of other primates, and the concepts that symbolic speech (including sign language) can represent far outnumber those that any other living creature can transmit to another.

In his *Descent of Man*, Charles Darwin hypothesized that language enabled our intellect to evolve to be more complex than our relatives, and this remains a strong hypothesis. Cortical regions of the human brain—those that are dedicated to controlling the biomechanical production of speech and also to crafting, receiving, and perceiving language—prove how strongly tied language is to the evolution of our large brains. The ability to share knowledge and to think symbolically allowed humans to learn, retain, and synthesize immeasurably more infor-

mation than their ancestors and other species. Speech and language have been intimately intertwined with encephalization and brain organization in evolutionary history.

Because encephalization beyond the size of chimpanzees begins with the genus *Homo* about two million years ago, it is possible that language abilities evolved hand-in-hand since then. Neurological anatomy can be tracked through the hominin fossil record, but so far it has not been used to successfully pinpoint the origin of language. Based on reconstructions of the throat and vocal tract from fossil skulls and skeletons, it appears as though this anatomy was not humanlike until about 50,000 years ago and only in modern humans, not in Neanderthals who were also living at that time.

The latest evidence for language origins comes from our DNA. People with the same mutation at the gene known as FOXP2 have difficulties with certain aspects of both speech and language. Although FOXP2 is involved in the development of vocalization in many animals, like birds and mice, it has undergone strong natural selection in humans over the past 100,000 years. This estimate, based on genetic differences between humans from different populations all over the world (a method known as molecular clock analysis), suggests that language evolved before the throat anatomy was fully modern. What is interesting is that ancient DNA from

Neanderthals actually contains the same version of the gene found in humans. Furthermore, it appears that once language became important, the cognitive aspects were selected (e.g., as seen in FOXP2) before the anatomy was perfected (e.g., as seen in the fossil record). The implications of this scenario are twofold: (1) the earliest hominin speakers could not make the full range of sounds that humans are capable of making today, and (2) once human vocal anatomy evolved—the same anatomy that causes adults of our species to incur a high risk of choking on food—the selection pressure was stronger for speech than it was against choking, so the anatomy persisted.

Thus, at some point between 100,000 and 50,000 years ago, humanlike speech emerged, and this dovetails with an explosion of symbol use in the archaeological record. But what caused complex oral communication to begin in the first place?

It is not just throat anatomy that is keeping trained chimpanzees and gorillas from having language. They learn thousands of words and symbols, which includes sign language for some, yet even when armed with such a vocabulary they are unable to use words and symbols in millions of syntactic combinations as we do. Cognitive differences are certainly at play, but there may be something crucial about actually speaking words. Early hypotheses for language evolution claimed that learning to manufacture stone tools required oral instruction or that hunting required complex communication that only language could provide. Yet these hypotheses have lost strength. More recently, Dean Falk hypothesized that baby talk, or “motherese,” between a mother and infant was the first step to human language. Robin Dunbar suggested that gossip may have replaced grooming (e.g., like baboons preening one another’s fur) in hominin evolution, especially when we started to live in large groups when vocal “groomers” could simultaneously interact vocally (rather than physically) with multiple individuals and could spread information over a vast network.

What Biology Tells Us of the Structure of the Brain and Its Capacity for Speech

When we are looking for the capacity for speech, we have to go back in time to earlier hominid species. Our predecessors in the history of evolution had that capacity. These were the Neanderthals, as the archaic humans were called after the place of the earliest find, in 1856, of their remains. Archaic humans (or archaic *Homo sapiens*, respectively) were attributed different roles in human history. In the past, they were mostly degraded as primitive, savage, and unintelligent. Insights from recent research have revolutionized the image of these ancestors.

Today, it is known that the Neanderthals were inventive, had a sense for abstractness, adorned themselves with necklaces and pendants, shared beliefs about the afterlife, and might have even participated in the improvement of the lithic tool industry of the Cro-Magnon population in western Europe during the time of the transition from the Middle to the Upper Paleolithic Age (ca. 45,000–35,000 BCE). The Cro-Magnon were the earliest modern humans to live in Europe. The Neanderthals lived both in cohabitation with and in separation from modern humans for several thousand years.

The more we learn about the Neanderthals, their living conditions, and their achievements, the more we are able to theorize about the trajectory of evolution and especially about the capacities (and limitations) of our own species. Much of what we think is typical of modern humans finds its roots in the behavioral patterns and the cultural horizon of the Neanderthals. Among the abilities that we modern humans share with archaic humans is symbolic activity and the ways in which the brain operates for producing speech.

Scientific findings have provided proof that Neanderthals could speak and use a rudimentary language. These findings have raised some questions regarding the relationship between modern humans and their ancestors in terms of brain capacity and structure. What are the differences between the brain of modern humans and that of archaic humans? Do they diverge in their structures or in the ways they operate or in both? There was a time when scientists thought that the difference between the species in question was the size of their brain. According to modern findings, the brain of the Neanderthals was about the same size as our brain. This means that the size of our brain is not decisive for the faculty of language and the quality of our language skills.

The opinion that the faculty of language and the ability to speak rely on the structure of our brain remains widely accepted. This would speak in favor of the physical architecture of our brain as the major arbitrator of these mental capacities. Our brain is divided into a right and a left hemisphere. Neurology tells us that the left hemisphere of the brain is more active than the right hemisphere when we use language. This, however, does not mean that the multiple ability to utter linguistic sounds, to connect them into conventional molds of meaningful elements (i.e., words), to select from a repertory of lexical items to word the world, and to produce patterns of word order to form intelligible sentences would “reside” exclusively in the left hemisphere.

It has been a matter of priority for neurological research to identify certain areas in the brain that are allegedly responsible for linguistic operations. The most popular of these approaches is the so-called Broca-Wernicke language organ theory. This theory identifies two specific areas (called after their discoverers the Broca area and the Wernicke area) on the cerebral cortex as the “center” of language. The Broca-Wernicke theory cannot account for the wholeness of linguistic performance. This “center” may be responsible for most of the programming of the motorics of speech sounds. However, language skills are much more comprehensive than the part of motorics controlling utterances. Furthermore, clinical experience has shown that the faculty of language is not defunct in patients

whose brain is damaged in or around the Broca-Wernicke areas.

Some modern linguistic theories look for an explanation of the mechanism of language in assuming that a kind of “module” functions in the human brain that is programmed exclusively for linguistic performance. Such modular theories draw on the analogy of how computers operate and how their goal-oriented programs work. Although a modular theory pinpoints a program—not a specific section—for the brain, it looks for independent linguistic procedures, distinct from other brain activity.

Linguistic performance is an activity that belongs to the range of complex behavior. In order to account for the totality of such behavior, it seems futile to postulate certain areas of the brain as major gravitations or assume a specific programming.

Seemingly, those theories have a greater explanatory value that assumes linguistic operations to be effected by a comprehensive neurological process, with multiple activity of the synaptic network. From the standpoint of evolution, this means that the faculty of language did not evolve in segregation from other abilities but rather evolved as a result of a rise in dynamics and effectiveness of the overall brain capacity. This would speak in favor of a coevolution of language and the human brain, from the stage of primary consciousness among Neanderthals to that of higher-order consciousness in our species.

Further confirmation of the validity of comprehensive and integrated theoretical approaches comes from molecular genetics. A “language gene,” called FOXP2, has been identified that is involved in verbal apraxia (Greek for “inaction”). The involvement of this gene in processes of blocking linguistic performance concerns brain activity as a whole neither in sections nor relating to certain module programs.

How Do Our Nearest Primate Relatives Communicate?

In an evolutionary perspective, hominids are a branch of the primates. The australopithecines are the last of our common ancestors. Their brains were still apelike, and their behavioral skills lacked the complexity that we find in later hominid species.

When reflecting on communication in primates other than hominids, we have to be aware of their needs to communicate. All primates are social animals, which means that they live in groups of different size, and interaction in social groups requires systems of signs. The conditions of animal communication can be described as follows.

In order to properly assess the means of communication among our primate relatives and the difference between simple and complex communication, it is important to note the exclusiveness of human communication. Modern humans have devised a multitude of means of communication for use in a world whose social, cultural, and economic organizations are becoming more and more complex. Complex language is the most effective of the communicational systems, and this is exclusive to our species.

In addition to language, modern humans use many other systems of communication. From the standpoint of cultural evolution, communication by means of language evolved out of a milieu of nonverbal communication, that is, out of the interaction with meaningful gestures and poses. We have not lost the capacity of nonverbal communication (popularly called body language). Like other hominids before us, we communicate with movements of our hands, with different facial expressions, and with poses of our body.

There is another means of nonverbal communication that we have also inherited from our

hominid ancestors, and this is tactile communication (e.g., holding hands as an expression of intimacy, hugging as an expression of affection, kissing someone's cheeks as a friendly greeting). The trajectory of nonverbal communication (i.e., gestural code, tactile means with symbolic meaning) connects our behavior with that of other hominids and with primate species. Within the hominid branch of the primates the ability for nonverbal communication goes back to the australopithecines, some 4.5 million years ago. Among the nonhominid primates, nonverbal communication assumes more and more specific traits for each species. And yet there is a difference in the performance of nonverbal means among modern humans when compared to nonhominid primates. By virtue of their intentionality, modern humans can train their personal repertory of gestures and poses to make them effective tools in personal communication (e.g., facial expressions of a politician giving a public speech).

Communication in ape species may be limited to the use of simple signals to get attention like "Do this," "Don't do that," or "Come here," or their composition may be more varied with the use of gesturing signs with symbolic meaning. Humans use dozens of such nonverbal gesturing symbols, while in nonhominid primates the number is smaller. This is ultimately due to the fact that the social systems of apes are less complex than human societies, which have produced more refined systems of communication.

Since the late 1960s, behavioral scientists have conducted experiments with chimpanzees, testing their capability of language production. The means of communication have been visual, focusing on either the gesturing code or the stimulus-response mechanism (pressing symbols on a keyboard). In recent years, such experiments have been carried out also with other ape species, orangutans and monkeys. All the ape species on which behavioral experiments have been conducted show an astounding capacity for adjustment to human language.

The insights from such experiments confirm that there is an innate capacity for the use of symbols in the functioning of the brain in primates. This capacity can be directed, through behavioral training, explicitly toward human language. It has to be noted, however, that the

faculty of symbol using related to language is dormant in nonhominid primates (apes), and this ability is not activated under the conditions of their natural habitats. Humans need complex communication, verbal and nonverbal, while apes do not.

The Biology of Speaking—Australopithecines and Early Human Speech

Human speech is an articulation of sounds produced by the human voice in order to express words with symbolic meanings. Sound patterns created by the voice are specific to each speech community. For instance, the sound patterns of American English are specific and distinct from British English and other languages such as French, Russian, or Chinese. Speech is the wholeness of an utterance (or of a series of utterances) in the context of interaction (speech act). The realization of speech relies on anatomical features in the mouth, throat, and chest that coordinate the production of linguistic sounds.

Speech is only one among several forms of linguistic expression, although it is a major manifestation of information technology. Human language is fully operational even without spoken utterance. Linguistic messages can be

conveyed with the help of a gestural code or in writing. Moreover, inner language (imaging the inner world) is tacit and remains unexpressed to outsiders.

From the standpoint of the evolution of language, the transfer of information was not the main driving force behind the evolution of human speech. The need to develop social relations in the community most probably directed the evolutionary trajectory of linguistic skills.

In the process of the production of speech (the speaker's role) and of the reception of speech (the listener's role), various mental abilities and physiological activities operate in a symbiotic way. These activities include the following (ranging from the most general to the most specific):

- As a form of symbolic activity, objects of the real world are associated with an arbitrary sound sequences (e.g., the idea of a mountain is connected to the sound sequence *mountain* in English, *montagne* in French, *Berg* in German, or *gora* in Russian), ideas that cannot be visualized are related to lexical items (e.g., the idea "mother" is related to expressions such as *mother* in English, *äiti* in Finnish, or *okasan* in Japanese), and abstract ideas are expressed in words (e.g., peace, love, doubt, inventiveness, or vision).
- Motoric activity transmits the contents of an intended message to the motoric system and coordinates the voice and the movements of the tongue in order to mold spaces for the articulation of distinct sounds in the oral cavity.

In view of these preconditions, it becomes apparent that speaking is a complex human behavior in which the neural circuits of the brain and various physiological activities need to be activated to function in a symbiotic interplay. As for the evolution of human capacities relating to speech, the question has to be answered which of the primate species possessed the capacities required to accomplish this kind of complex behavior.

The reconstruction of the faculty of language and of the ability to speak includes the cultural horizons of archaic humans (*Homo*

neanderthalensis) and possibly even *Homo erectus*. Symbolic activity is evidenced for *Homo erectus*. Evidence for symbolic activity by hominid species is found on objects that were intentionally incised with notches. Such a manifestation of the abstract mind is unknown for other hominid species that existed before *Homo erectus*, more than 1.5 million years ago.

Since the capacity for symbolic activity is seemingly absent in earlier hominid species, the most basic precondition for language is missing. This means that *Homo ergaster* at 1.6 million years BP, *Homo rudolfensis*, and other species could not communicate by means of language. Language is also absent from the repertory of behavioral skills in *Homo habilis*, the first hominid species to use natural objects as tools and to produce crude stone tools. The stone tool industry began with *Homo habilis* approximately 2.6 million years ago. Although *Homo habilis* possessed practical skills, their mind was obviously not capable of symbolic performance.

While the neural activities of hominid species predating *Homo erectus* remained below the threshold of symbol making, certain constituents in the architecture of their brains that control the motorics of speech organs seem to have been in a state of developing:
